ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of poly vinyl alcohol and Poly ethyl Urethane to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Poly vinyl alcohol, Poly ethyl Urethane

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.However, the polyvinyl alcohol (PVA) hydrogel is an intriguing hydrogel, which has been investigated as a promising substitute for repairing diseased or damaged articular cartilages, meniscuses and tendons due to its excellent biocompatibility, low toxicity and water absorption abilities [8-9]. Moreover, the researchers have used polyethylurethane polymers were chosen as drug carriers for α-tocopherol. This active ingredient is widely used as a strong antioxidant in many potential applications including medical and cosmetic, but is rapidly degraded, because of its light, heat and oxygen sensitivity [10]. This study is intended to identify the interaction of polyvinyl alcohol and polyethyl urethane to form blends.This study is intended to identify the interaction of poly vinyl alcohol and Poly ethyl urethane to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of poly vinyl alcohol_and Poly Ethyl Urethane were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of poly vinyl alcoholon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly vinyl alcohol and Poly Ethyl Urethane as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties.For many years, group additive methods have been used to predict the properties of polymers and of small molecules. These methods are extremely fast and easy to use. Consequently, they are most useful when a rapid estimation of a property is needed without a thorough understanding of the atomic interactions that result in it. The key shortcoming of these approaches, however, is their dependency on a database of group contributions. Consequently, if a polymer includes a group for which the group contribution can not be determined, then that polymer 's property can not be measured.

To overcome this constraint, the method applied in Synthia uses topological polymer information in predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no group contribution database is needed and properties for any polymer composed of any combination of the following nine elements can be predicted: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine , bromine.

Bulk modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Shear modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol

Young's modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Poisson ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle fracture stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs.Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of poly vinyl alcoholand Poly ethyl urethane to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

Keywords: Poly vinyl alcohol, Polyoxy ethylene

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Vinyl polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxilla facial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, super absorbent polymer, ion-exchange resin, etc.[10].Polyvinyl alcohol is a polyelectrolyte soluble in aqueous media at neutral pHIt is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Further, the polyvinyl alcohols (PVA) are a water soluble polymer and also susceptible of ultimate biodegradation in the presence of suitably acclimated microorganisms. Besides, this polymer blends possess good thermal stability [12]. Besides, Polyoxyethylene surfactants are widely used as emulsifying agents and detergents. This ionic surfactants form micelles above a critical concentration in water with liquid crystals frequently occurring at higher concentrations [12]. This study is intended to identify the interaction of polyvinyl alcohol and polyoxyethylene to form blends.

Researchers have used polyoxyethylene in combination with other materials to act as adsorbent [12]. polyoxyethylene have been reported to be used in Curtius reaction. This study is intended to identify the interaction of polyvinyl alcohol and polyoxyethylene to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyoxyethylene were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcoholon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyoxyethylene as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties Asha Rani Dalai and Subhraraj Panda may be predicted for any

polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Shear modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Young's modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Poisson ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle fracture stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyoxyethylene to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.vinyl polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denturerepair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10].Polyvinyl alcoholis a polyelectrolyte soluble in aqueous media at neutral pH. It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have used polyoxymethylene in combination with other materials to act as adsorbent [12]. However, the physical properties of polyoxymethylene changes which occur during the rolling process of these polymers and these polymers possess good thermal and mechanical properties [13]. This study is intended to identify the interaction of polyvinyl alcohol and polyoxymethylene to form blends. This study is intended to identify the interaction of poly Vinyl alcohol and polyoxymethylene to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcoholand polyoxymethylene were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcoholand polyoxymethylene as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Shear modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of Vinyl alcohol.

Young's modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of Vinyl alcohol.

Poisson ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of Vinyl alcohol.

Brittle fracture stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of Vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyoxymethylene to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of Vinyl alcohol. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyacrylic acid and polyacrylonitrile to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyacrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyacrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Poly acrylic acid, Polyacrylonitrile composite

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working

on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Among the various polymers, polyacrylic acid is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of polyacrylic acid is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, polyacrylic acid is non-toxic, good adsorbent, hydrophobic, biocompatible and used as electrolyte [11]. Researchers have used polyacrylonitrile (PAN) is a carbon fiber precursor and is also used for activated carbon. However, the carbonized and activated electrospun PAN fibers are attractive for supercapacitor electrodes, catalysis, and other applications [12]. This study is intended to identify the interaction of polyacrylic acid and polyacrylonitrile to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyacrylic acid and polyacrylonitrile were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acid on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polymer X as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of

group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

Permeability of gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the mebrane. Figure 3 shows that the permeability of oxygenthrough the composite decreases with increase in mass fraction of acrylic acid.

Figure 4 shows that the permeability of nitrogenthrough the composite decreases with increase in mass fraction of acrylic acid. Figure 5 shows that the permeability of carbon dioxidethrough the composite decreases with increase in mass fraction of acrylic acid. Thus the results indicated that an increase in acrylic acid fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyethyl urethane to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

The impedance and modulus study is performed at room temperature for different frequency ranges. The grain and grain boundary are responsible for conduction mechanism of $SrTiO_3$ by impedance spectroscopy. The dielectric and electrical properties of this material is strongly dependent on temperature and frequency. Jonscher's universal power law was followed by dependence of ac conductivity on frequency at different temperatures.

Keywords: Solid state reaction; Modulus; Impedance; AC conductivity;

INTRODUCTION

In recent years, Strontium titanate (STO) has gained a lot of attraction in the field of electronics because of itssignificant electro-chemical properties. It has high dielectric constant, high melting temperature, low coefficient of thermal expansion[1]. It is a ferroelectric perovskite material with face centered cubic structure[2]. Moreover, STO is an important band insulator because it has a band gap = 3.2 eV[3].It plays a vital role in photo-catalysts in solar cells, and solid oxide electronic devices[4]. It has been used in various microwave application because of its dielectric nonlinearity nature(dielectric constant depends on applied electric field) [5]. It has a vast application in the fields of RF filters, hydrocarbon sensors and antennas[6]. Doping of transition metals like Cu can enhance its ferroelectric properties. Cu oxide is a p-type semiconductor with 1.2 eV[7]. Cu doping can significantly affect its transport properties such as enhanced dielectric constant, low dielectric loss, improved ac conductivity, etc. [8]. There are several methods to synthesize STO but in this work, we have followed solid state methodto synthesize Cu doped STO ceramic powders and then made composite of these ceramic-polymers with the help of PMMA polymers by solution casting method and studied about how the Cu doping affects its electrical impedance and complex modulus which can give us an idea about the grain boundary, overall electrical properties, relaxation period, bulk properties and the various types of polarization occurring inside the material.

Experimental

The ceramic powders of Cu doped $SrTiO_3$ were prepared using high-temperature solid state reaction technique using high-purity stoichiometry ingredients. The structure weighed stoichiometrically was carefully blended, first for 2 hours in an air atmosphere and then for another 1 hour in alcohol. Then the mixed powders were calcinated at an optimized temperature of 950ºC for 4hr in a high purity alumina crucible. At first 0.025g of $(Pb_{0.5}Cu_{0.5})TiO_3$ was taken in a crucible and heated it for two hours with a temperature of 150ºC.Then the powder was grinded for 30 mins. Then 20ml of N, N-Dimethylformamide was taken in a conical flask and 5g of PMMA was added to it. The mixture is left at ambient temperature for 20 minutes under continuous magnetic stirring until a homogenous mixture is formed. Then to the above mixture stoichiometric (0.025g) amount of ceramic powder ($(Pb_{0.5}Cu_{0.5})TiO_3$) was added. Again, the mixture was stirred for 1hr and a homogeneous mixture was obtained. Then the homogeneous mixture was casted on glass Petridis and heated in a hot air oven at 120ºC for 4-5 hours. Finally, the polymer film was obtained.

RESULT AND DISCUSSION

Impedance Study

In order to analyze the transport properties of the material and nature of the material response, complex impedance analysis study is used [9] such as study the real and imaginary parts of some complex parameters impedance, modulus, etc. From the fig.1(a) we can analyze the variation of real part of impedance with frequency. It shows large value of impedance at lower frequency region but as soon as the frequency increases the impedance value falls suddenly and almost after 9 KHz onwards it attends saturation. Relatively low value saturation frequency indicates that heavier ion/dipole may be associated with some switching. This suggests the presence of mixed nature of polarization behavior in the material, such as electronic, dipolar and orientation polarization. These results indicate a possibility of increase in ac conductivity which is due to the release of space charge and lowering in the barrier properties of the material. Again, from graph 1(b), the variation of imaginary part of impedance with frequency can be studied. Here the value of Z"increases rapidly from the negative axis with increase in frequency and reaches a saturation at 20 KHz. This may happen due to presence of some voids.

Modulus Study

Fig.2(a) shows the variation of real part of modulus (M') with frequency which shows a dispersion tending towards M′ (the asymptotic value of M' at higher frequencies) and the dispersion shifts towards higher frequency sideas the frequency increases. The asymmetric plot of M' is because of the stretched exponential character of relaxation time of the material. The monotonous dispersion on increasing frequencymay be because of short range mobility of charge carriers. This is may be due to lack of restoring force governing the mobility of the charge carriers under the action of an induced electric field [10]. On the other hand, the variation of imaginary part of modulus (M") can be explained by fig.2(b). From this graph it can be seen that at higher frequency range M" shows a strong peak at 2000KHz. The frequency region below peak maximum M" determines the range in which charge carriers are mobile on long distances. At frequency above peak maximum, the carriers are confined to potential wells, being mobile on short distances.

Conductivity Study

Fig.3 explains the variation of ac conductivity with frequency. It increases with increase in frequency and between reaches a maximum value of 4.934 ohm-1m-1 at a frequency of 4000kHz. At low frequency the charge accumulation at the electrode-interface takes place which reduces the conductivity. The high frequency region of the ac conductivity is frequency independent due to the random diffusion of the ionic charge carriers and the values correspond to dc conductivity.

CONCLUSION

The ferroelectric composites of Cu doped $SrTiO_3$ are successfully prepared by high-temperature solid state technique. The doping of Cu enhances the conductivity of the composite. These studies reveal a significant contribution of grain and grain boundary effect in the material. The frequency dependent real impedance shows that at low temperature region space charge polarization is released.

ABSTRACT

A blend is formed with the combination of two or more components. The compatibility of polyvinyl alcohol and polyoxy ethylene were studied to form a miscible blend with the tool, Biovia Materials Studio. The compatibility of the two components was verified with free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at high temperature. Phase diagram indicated that a single phase can be obtained above 700 K which was the critical temperature. The coordination number was found to be 5.69 +/- 0.04. The highest number of configurations with respect to energy level was found to be -1.95kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend, *In silico*, polyvinyl alcohol, polyoxy ethylene.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. Since it is very rare to find multiple properties in a pure material, so one can combine different components for improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering owing to its high value of strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method andthis technique is a low cost and less time consuming method. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Polyvinyl alcohol (PVA) isone of the most interesting material owing to its high value of dielectric strength, adhesiveness,easy film formation and also its properties can be improved by various dopant concentrations [8, 9]. Strong polymeric films are produced for the packaging industry since PVA film is easy to fabricate.This is owing to their high mechanical strength, highly stable and can be easily processed [10]. In addition, PVA is non-toxic, hydrophilic, semi crystalline, biocompatible and easily soluble in water [11].Researchers have found applications of polyvinyl alcohol (PVA) are a water soluble polymer and also aresusceptible for biodegradation, in the presence of acclimated microorganisms. Besides, this polymer blends possess good thermal stability [12]. On the other hand, Polyoxyethylene surfactants are popularly used as emulsifying agents and detergents. Above a critical concentration, this ionic surfactants form micelles in water, with liquid crystals forming at higher concentrations [13]. This study is intended to identify the interaction of polyvinyl alcohol and polyoxyethylene to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software package (Dassault Systemes of France) was used for this work and its analysis. The software uses machine learning techniques and standard algorithms to predict the results.

Methodology: Polyvinyl alcohol and polyoxyethylenewere prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and polyoxyethylenewas used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyoxyethylene as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy: A blend is known as amiscible if it is homogeneous. If the free energy has a negative value that indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$\Delta G_m = \Delta H_m \quad T\Delta S_m$ (1)

where ΔG_m = Gibbs free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = Entropy of mixing

T = Absolute temperature

The value of $T\Delta S_m$ is always positive in case of a blend as the entropy increases after the mixing. Thus, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components gets added to form a miscible blend only when the contribution of entropy to free energy is more than the contribution from enthalpy, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always negative or less than zero for the temperatures studied. The free energy is inversely proportional to temperature (upto 275 K) as evident from Eq. 1 and then free energy increases with increase in temperature. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyvinyl alcohol and poly polyoxyethylene with negative value of mixing energy, which may lead to form a perfect blend with significantly less effort.

Chi Parameter: The free energy of mixing is described by the Flory–Huggins χ parameter and helps to explain phase behavior for polymer blends and block copolymers. The polymers which are not chemically similar, a significant difference in cohesive energy density leads to a high χ value and that indicates a larger driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture to occupy the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in stiffness of the chain for chemically similar components may lead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating de-mixing. The χ value decreased with increase in temperature.Thus at high temperature there is a possibility to form a miscible blend.This agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated considering all possible molecular pairs those are involved in the molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used off-lattice calculations. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only in case of the components of the binary blend having similar volumes or similar surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are of different sizes. In this study the coordination number was found to be 6.97 +/- 0.04.

Phase Diagram: The phase diagram is used to understand the compatibility of binary mixtures. Figure 3 shows the phase diagram for the two components of the blend. There are three regions with different degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 750 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 750 K).

b. Fragmented metastable region existed inbetween binodals region and spinodals region, and

c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the met stable and two-phase region.

When the system moves from single-phase to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e., slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 5 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.95kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 6 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy. It also shows that mixing energy gradually increases with increase intemperature with varying the temperature from 50 K to 500 K. So, it is very much possible to mix the two components at any feasible temperature with least mixing energy value. The formation of non homogeneous blend with polyvinyl alcohol as base might help formation of blend with high mechanical strength. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyoxy ethylene to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 5.69 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -1.95kcal/mol. usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is formed with the combination of two or more components. The compatibility of polyvinyl alcohol and Polyoxym ethylene were studied to form a miscible blend with the tool Biovia Materials Studio. Compatibility of the two components was verified with free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at high temperature. Phase diagram indicated that a single phase can be obtained above 700K which was the critical temperature. The coordination number was found to be 4.97 +/- 0.04. The highest number of configurations with respect to energy level was found to be -2.3 kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend, *In silico*, polyvinyl alcohol, polyoxymethylene

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working

on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high value of strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method andthis technique is a low cost and less time consuming method. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Polyvinyl alcohol (PVA) isone of the most interesting material owing to its high value of dielectric strength, adhesiveness, easy film formation and also its properties can be improved by various doping of different concentrations [8, 9]. Strong polymeric films are produced for the packaging industry since PVA film is easy to fabricate.This is owing to their high mechanical strength, highly stable and can be easily processed [10]. In addition, PVA is non-toxic, hydrophilic, semi crystalline,biocompatible and easily soluble in water [11]. Researchers have found the most dominating property of polyvinyl alcohol is thermal resistance [12]. However, the physical properties of polyoxymethylene changes which occur during the rolling process of these polymers and these polymers possess good thermal and mechanical properties [13]. This study is intended to identify the interaction of polyvinyl alcohol and polyoxymethylene to form blends.

MATERIALS AND METHODS

Software Used: For this work the Biovia software tool has been used. Its a software tool developed by DassaultSystemesof France. All analysis were done by Materials studio that is a module of Biovia software. The software uses machine learning techniques and standard algorithms to predict the results.

Methodology: Polyvinyl alcohol and polyoxymethylene were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and polyoxymethylene was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol andpolyoxymethylene as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy: A blend is known as amiscible if it is homogeneous. If the free energy has a negative value that indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = Gibb's free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = Entropy of mixing

T = Absolute temperature

The value of $T\Delta S_m$is always positive in case of a blend as the entropy increases for mixing. Thus, the sign of $\Delta G_m$is found to depend on the value of the enthalpy of the mixing ΔH_m. The components gets added to creat a miscible blend only when the contribution of entropy to free energy is more than the contribution from enthalpy, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always negative or less than zero for the temperatures studied. The free energy is inversely proportional to temperature (upto 275 K) as evident from Eq. 1 and free energy increases with increase in temperature. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyvinyl alcoholand poly polyoxymethylene with negative value of mixing energy, which may lead to form a perfect blend with significantly less effort.

Chi Parameter: The free energy of mixing is described by the Flory–Huggins χ parameter and helps to explain phase behavior for polymer blends and block copolymers. Thepolymers which are not chemically similar, a significant difference in cohesive energy density leads to a high χ value and that indicates a larger driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture to occupy the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature.Thus at high temperature there is a possibility to form a miscible blend.This agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated considering all possible molecular pairs those are involved in the molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used off-lattice calculations. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only in case of the components of the binary blend having similar volumes or similar surface areas. It is difficult to apply the pairs method to define the coordination number for a binary system in which the components are not comparable in size. In this study the coordination number was found to be 4.97 +/- 0.04.

Phase Diagram: The phase diagram is used to understand the compatibility of binary mixtures. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:
a. The single-phase miscible region existed above the critical temperature of around 750 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 750 K).
b. Fragmented metastable region existed in between binodals region and spinodals region, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region. When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase to the spinodal region of immiscibility the phases separate automatically by a methodknown as spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 5 shows the plot of frequency (P(E)) against energy levels. It shows

that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.00 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 6 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy. It also shows that mixing energy gradually increases with increase intemperature with varying the temperature from 50 K to 500 K. So, it is very much possible to mix the two components at any feasible temperature with least mixing energy value. The formation of nonhomogeneous blend with polyvinyl alcohol as base might help formation of blend with high mechanical strength. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcoholand polyoxymethylene to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 4.97 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -2.3 kcal/mol. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one components. The desired property of a blend is its homogeneity. The composition of polyvinylalcohol and urea to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, *In silico*, polyvinyl alcohol, Urea composite

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering owing to its high value of strength to weight ratio and resistance to corrosion.Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Polyvinyl alcohol (PVA) isone of the most interesting material owing to its high value of dielectric strength, adhesiveness, easy film formation and also its properties can be improved by various dopant concentrations [8, 9]. Strong polymeric films are produced for the packaging industry since PVA film is easy to fabricate.This is owing to their high mechanical strength, highly stable and can be easily processed [10]. In addition, PVA is non-toxic, hydrophilic, semi crystalline, biocompatible and easily soluble in water [11]. Researchers have used polyvinyl alcohol in combination with other materials to act as adsorbent [12].Also, the elastomeric thermoset polyurea has severallatest applications,like, increasing the life of structures under heavy loading and withstanding the case of blast and ballistic events [13]. This study is intended to identify the interaction of polyvinyl alcohol and urea to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software package (Dassault Systemes of France) was used for this work and its analysis. The software uses machine learning techniques and standard algorithms to predict the results.

Methodology: The structures of polyvinyl alcohol and urea were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and urea as potential components of a composite was analyzed using Materials Studio of Biovia. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a various polymer properties.Since long, group additive methods were used to study the properties of polymers and also that of small molecules. These methods are very fast and can be handled with ease.That is why they are popular especially forquick estimation of properties without going to the details of the intermolecular interactions which is actually the basic cause of it. However, the main drawback of these methods is their dependence upon a database of group contributions. Thus, in case of a polymer that contains a group, for which the group contribution cannot be predicted, then the properties of that polymer cannot be estimated.

To overcome this limitation, the method used in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices obtained from graph theory are used here. Thus, no database of group contributions is required and the properties can be estimated for any polymer consisting of any combination of the elements: C, H, N, O, Si, S, F, Cl and Br.

Molar volume: The volume occupied by one mole of a substance is called its molar volume. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of polyvinyl alcohol

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Permeability of gas: under equilibrium condition, we can deifne Permeability as the rate at which the gas can pass through the polymer membrane. Lower permeability indicates longer time lag for the gas to pass through the mebrane. Figure 3 shows that the permeability of oxygenthrough the composite decreases with increase in mass fraction of Vinyl alcohol

Figure 4 shows that the permeability of nitrogenthrough the composite decreases with increase in mass fraction of Vinyl alcohol. Figure 5 shows that the permeability of carbon dioxidethrough the composite decreases with increase in mass fraction of Vinyl alcohol. Thus the results indicated that an increase in Vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyurea to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume and density decreased with increase in polyvinyl alcoholfraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of polyvinyl alcoholusually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Ceramic powders of Cu doped Lead titanate ($Pb_{0.5}Cu_{0.5}TiO_3$) are synthesized through high temperature solid state reaction method. 5% of ceramic filler in to the polymer matrix was prepared by solution casting techniques. The Impedance studies of this polymeric composite were characterized by LCR meter in the wide range of frequencies from 10^2-10^6 Hz at room temperature. Moreover, Modulus study of the material can be done between the frequency ranges 10^2-10^6 Hz. Moreover, the Jonscher's universal power law was followed by dependence of ac conductivity on frequency at different temperatures.

Keywords: Solid state reaction; Modulus; Impedance; AC conductivity;

INTRODUCTION

In recent decades, materials scientists are showing much more interest in the development of new multifunctional ceramic, polymer, polymeric composite for various applications in the fields of electronics and optoelectronics. Keeping an eye on the above demands, polymeric crystals, especially ferroelectric polymer-ceramic composites has gained a huge attention due to their significant role in the devices like thin film capacitors, electronic transducers, pyroelectric sensors and nonlinear optics etc [1].

A composite is a mixture of two or more different materials of different phases having different properties which produce the desired material which may not be achieved in single-phase materials [2]. Ferroelectric polymer ceramics have been in demand because of their significant properties which make them ideal for photovoltaic process which is core concept of the energy storage devices [3]. The electrical energy density can be expressed by the formula $U = (\varepsilon r Eb^2)/2$ where εr is the dielectric constant of the material and Eb is the breakdown strength. To increase the electrical energy storage capacity, both high value of dielectric constant and large coefficient of breakdown strength are needed. Ceramic materials have high dielectric constant but their stiff and brittle nature make them lack in breakdown strength. On the other hand, polymers have low dielectric constant but large breakdown strength which makes them flexible so if the large dielectric constant of ceramics and high breakdown strength can be combined together then a suitable material for the energy storage application will be obtained [4].

Experimental Technique

The ceramic powder of Cu doped $PbTiO_3$ was prepared using high-temperature solid state reaction technique using high-purity stoichiometry ingredients. The structure weighed stoichiometrically was carefully blended, first for 2 hours in an air atmosphere and then for another 1 hour in alcohol. Then the mixed powders were calcinated at an optimized temperature of 950°C for 4hr in a high purity alumina crucible. Initially, 0.025g of $(Pb_{0.5}Cu_{0.5})$ TiO_3 was taken in a crucible and heated it for two hours with a temperature of 150°C.Then the powder was grinded for 30 mins. Then 20ml of N, N-dimethylformamide was taken in a conical flask and 0.5g of PMMA was added to it. The mixture is left at ambient temperature for 20 minutes under continuous magnetic stirring until a homogenous mixture is formed. Then to the above mixture stoichiometric (0.025g) amount of ceramic powder $[Pb_{0.5}Cu_{0.5})TiO_3]$ was added. Thus, the mixture was stirred for 1hr and a homogeneous mixture was obtained. Then the homogeneous mixture was casted on glass Petridis and heated in a hot air oven at 120°C for 4-5 hours. Finally, the polymer film was obtained. For electrical measurements, the polymer film faces were coated with high purity silver paste and dried at 100°C. The formation and structural properties of the compounds were studied by X-Ray diffraction (Rigaku, Ultima IV). Dielectric and impedance measurements were performed using an LCR meter computed (Impedance analyzer, IM 3570).

RESULTS AND DISCUSSION

Impedance and Modulus Study

In order to analyze the transport properties of the material and nature of the material response, complex impedance analysis study is used [7] such as study the real and imaginary parts of some complex parameters impedance, modulus, etc., Fig.1 shows the variation of real part of impedance with frequency. It is observed that the large value of impedance at lower frequency region but as the frequency increases the impedance value falls suddenly and almost after 9 KHz onwards it attends saturation. Relatively low value saturation frequencyindicates that heavier ion/dipole may be associated with some switching. This suggests the presence of mixed nature of polarization behavior in the material, such as electronic, dipolar and orientation polarization. These results indicate a possibility of increase in ac conductivity, which is due to the release of space charge and lowering in the barrier properties of the material.

As shown in Fig.2, the variation of imaginary part of impedance with frequency can be studied. Here the value of Z"increases rapidly from the negative axis with increase in frequency and reaches a saturation at 20 KHz. This may happen due to presence of some voids. Fig.3 shows the variation of real part of modulus (M') with frequency which shows a dispersion tending towards M' (the asymptotic value of M' at higher frequencies) and the dispersion shifts towards higher frequency side as the frequency increases. The asymmetric plot of M' is because of the stretched exponential character of relaxation time of the material. The monotonous dispersion on increasing frequency may be because of short range mobility of charge carriers.This is may be due to lack of restoring force governing the mobility of the charge carriers under the action of an induced electric field [8]. On the other hand, the variation of imaginary part of modulus (M'') can be explained by Fig.4. As shown in Fig.4, it can be seen that at higher frequency range M'' shows a strong peak at 2000 KHz. The frequency region below peak maximum M'' determines the range in which charge carriers are mobile on long distances. At frequency above peak maximum, the carriers are confined to potential wells, being mobile on short distances.

Conductivity Study

Fig.5 shows the variation of ac electrical conductivity with frequency at room temperature. It is observed that the increases with increase in frequency and in between 2000 KHz to 3000 KHz range it nearly saturates and beyond this range, it again increases and reaches to a value of 1.3919 $ohm^{-1}m^{-1}$ at 4000 kHz. At low frequency the charge accumulation at the electrode-interface takes place which reduces the conductivity. The high frequency region of the ac conductivity is frequency independent due to the random diffusion of the ionic charge carriers and the values correspond to dc conductivity.

CONCLUSION

The ferroelectric composites of Cu doped $PbTiO_3$ are successfully prepared by high-temperature solid state technique. The doping of Cu enhances the conductivity of the composite. These studies reveal a significant contribution of grain and grain boundary effect in the material. The results demonstrate that the composites effectively improve the dielectric performance and thus providing an excellent candidate for the development of energy storage devices.

ABSTRACT

Combination of two or more components results in the formation of a blend. The compatibility ofvinyl alcohol andethylurethanewere studied to form a miscible blend using Biovia Materials Studio. The compatibility of the two components was demonstrated based on free energy of mixing, chi parameter,phase diagram andmixingenergy.The results indicated that the pair can become compatible at both low and high temperature. Phase diagram indicated that a single phase can be obtained above 387.5K which was the critical temperature. The coordination number was found to be 5.28+/-0.03. The highest number of configurations with respect to energy level was found to be-9.2kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend, *In silico*, Polyvinyl alcohol, Urethane

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method andthis technique is a low cost and less time consuming method. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Polyvinyl alcohol (PVA) is a promising material among the various polymers because of its high dielectric strength, easy film formation, adhesivity and the properties of which can be regulated by dopant concentrations [8, 9]. PVA's film forming capability is commonly used to form solid polymeric films in the packaging industryThis is due to their high mechanical strength, eco-stability and fast processing [10]. PVA is non-toxic, semi-cristalline, hydrophilic, biocompatible and easily water soluble [11].In addition, the polyethylurethane polymers were selected as α-tocopherol drug carriers.This active ingredient is widely used as a powerful antioxidant in many potential applications, including medical and cosmetic applications but is rapidly degraded due to its sensitivity to light , heat and oxygen [12]. The goal of this study is to identify the interaction between polyvinyl alcohol and polyethyl urethane in forming blends.

MATERIALS AND METHODS

Software Used: Biovia software (Dassault Systemes of France) materials studio module was used for the analysis.The software uses machine learning techniques and regular algorithms to forecast interaction rates.

Methodology: Vinyl alcohol andethylurethane were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and ethylurethane was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of vinyl alcohol and ethylurethane as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where $\Delta G_m = Gibbs\ free\ energy\ of\ mixing$

$\Delta H_m = Enthalpy\ of\ mixing$

$\Delta S_m = Entropy\ of\ mixing$

T = *Absolutetemperature*

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always negative or less than zero for the temperatures studied. The free energy decreases with increase in temperature (upto 275 K) as evident from Eq. 1 and free energy increases with increase in temperature. The results indicated that the blend will lead to ahomogenous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyvinyl alcoholand poly ethylurethane with negative value of mixing energy,which may lead to form a particular shape with significantly high effort.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi). Figure 2 shows that the value of x high from temperature ranging from 50Kto 500K Thevalue of x decreases exponentially with increase in temperature.This agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 5.28+/-0.03.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:
a. The single-phase miscible region existed above the critical temperature of around 750 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 750 K).
b. Fragmented metastable regions existed between binodals and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region. When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pair's method may lead to configurations of varying energy levels. Figure 5 shows the plot of frequency (P(E)) against energy levels. This shows that the distribution is somewhat symmetrical and long chain high energy level. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.00 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that at first when temperature increases the mixing energy increases to a highest value after that when again temperature increases the mixing energy becomes decreases and again further increases with increase in temperature.The temperature is vary from 50K to500K for the varying of mixing energy.it is very much possible to mix the two components at any feasible temperature with least mixing energy value.

CONCLUSION

The possibility of use of polyvinyl alcohol and ethyl urethane to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found 8.25+/-0.03. The maximum number of configurations with respect to energy level was found to -9.2Kcal/mol.Usually components for a blend is identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, *In silico*, Polyvinyl alcohol, Polyoxyethylene composite

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials[3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio

and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Further, PVA (polyvinyl alcohol) is an essentialpolymeric material which is universally benefitedin packaging industry to form strong polymeric materials and excellent film forming natures. because of itseasy formation of film, high dielectric strength,high mechanical strength, high thermal conductivity, stability of environment andadhesiveness etc. These properties of material can be fluctuated by various contentof dopant [8-10]. Meanwhile, the PVA is non-toxic, semi-crystalline, hydrophilic, biocompatible and easily soluble in water [11]. Furthermore, a molecular complexof high-molecular polyoxyethelene-urea mixtureswith respect to thermal behavior in between 20^0-500°Cwas explored by means of a derivatograph.This study is intended to identify the conversion of polyvinyl alcohol into a sponge-like material by foaming agents and hardened with formaldehyde and polyoxyethelene to form blends [12-13].

MATERIALS AND METHODS

Software Used

The software used for analysis was Materials studio module of Biovia (France Dassault Systemes). The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of polyvinyl alcohol and polyoxyethelene were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS & DISCUSSION

In this work the use of polyvinyl alcohol and polyoxyethelene as potential components of a composite was analyzed using BIOVIA Materials Studio which needs pre-defined correlations (advanced quantitative structure-property relationships) to figure out a broad range of polymer properties. The methods of Group additive were operated for many years to predict the properties of small molecules and polymers. For extremely fast property estimation without detailed knowledge of the atomistic interactions, these methods are of greatest utility and easy to operate. However, the principal drawback of these methods is the dependence upon the database of group contributions. Thus, without group contribution database the property of polymer cannot be determined.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, properties ofany polymer may be predicted without database of group contributions by the composition of any combination of the following nine elements: hydrogen(H), carbon(C), nitrogen(N), oxygen(O),bromine(Br), silicon(Si), sulfur(S), fluorine(F), chlorine(Cl).

Heat capacity: It is the amount of heat required without change of phase to raise the temperature of one-unit weight of a substance by 1°C. Figure 1 shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Dielectric constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyoxyethelene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of Vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, *In silico*, Polyvinyl Alcohol, Polyethylurethane composite

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were

developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7] have been used to identify compatible pairs. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. Due to extreme mechanical strength, eco friendly and easy fabrication process of PVA, it is mostly used in packaging industry to make strong polymeric film [8]. It also attracts the researcher because of its some excellent characteristics like semi-crystalline, hydrophilic, biocompatible and easily soluble in water [9]. Ethylurethane can be combined with other materials for drug delivery for α-tocopherol. It is also applicable in area of medicine and cosmetic as a strong antioxidant. Their application is limited due to its fast degrading nature because of environmental sensitivity [10]. So the objective of the work is to manifest the interaction of polyvinyl alcohol and polyethyl urethane to form blends.

MATERIALS AND METHODS

Software Used: Analysis was done by a software "Materials studio module of Biovia" (Dassault Systemes of France). The interaction level is predicted using machine learning techniques and standard algorithms of the software.

Techonic: The structures of Vinyl alcohol and ethylurethane were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of Vinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of Vinyl alcohol and ethylurethane as potential components of a composite was analyzed using "Biovia Materials Studio". "BIOVIA Materials Studio Synthia" uses preset connections (advanced quantitative structure-property relationships) to work out various characteristics of polymer. Earlier the properties of polymers and small molecules were estimated by group additive methods because of its simplicity and rapidness. But this technique suffers from certain drawbacks as it requires a large database. So the polymers of specific group can be characterized by this method.

So to study unknown polymers and its interaction with other materials Synthia method is adopted for topological information. The dependent parameters obtained from graph theory are shown. So a specific group contributions is not necessary for combination of a polymer with any following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat capacity: The thermal energy required to increase the temperature of unit mass of a substance by 1°C at a given phase is known as heat capacity. Figure 1 shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of Vinyl alcohol.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of Vinyl alcohol.

Dielectric constant: Dielectric constant is the fraction of increase of bound charges in the medium as compared to free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyethylurethane to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of Vinyl alcohol. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of Vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, *In silico*, Polyvinyl Alcohol, Poly urea composite

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials[3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were

developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.For dental implants, anddenture bases, dental repairmen, and for various skeletal defects Polyvinyl alcohol polymers are largely used [8, 9]. They are also used as dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10]. Moreover, these polymers have easy processing, low cost and wide variety of applications in the field electrical and electronic components. Polyvinyl alcoholis a polyelectrolyte soluble in aqueous media at neutral pH. It is used for preparing hydrogels. It is not toxic and does not cause irritation [11].

Researchers have used polyurea in combination with other materials to act as adsorbent [12]. Inaddition, the polyurea have elastomeric thermoset polymeric materials and has various new fields of militaryapplications because of its high mechanical strength [13]. This study is intended to identify the interaction of polyvinyl alcoholand polyurea to form blends.

MATERIALS AND METHODS

Software Used: The software "Materials studio module of Biovia" (DassaultSystemes of France) was adopted for analysis purpose. The interaction between different materials is studied via machine learning techniques and standard algorithms.

Working: The structures of polyvinyl alcoholandpolyurea were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcoholon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of Vinyl alcohol and ethylurethane as potential components of a composite was analyzed using "Biovia Materials Studio". "BIOVIA Materials Studio Synthia" uses preset connections (advanced quantitative structure-property relationships) to work out various characteristics of polymer.The conventional technique to study the polymer properties and its combination was group additive methods which was quite simple and fast process.But this technique has a big shortcoming that it requires a particular database for each component which is another difficult task..

.So the appropriate answer to the above difficulties is Synthia method for proper topological information.Again graph theory plays an important role along with the software to study unknown polymers and its interaction with other materials.So a polymer belongs to any group can combine with the given elements : carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine to form a composite.

Heat capacity: The energy supplied to increase the temperature of unit mass of the substance through unit range is called heat capacity**.** It is the amount of heatrequired to raise the temperature of one unit weight of a substance by 1°C without change of phase.Figure 1 shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient.It refers to the intrinsic ability of a material to transfer heat.Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Dielectric constant: The relative permittivity of a material with respect to air is the dielectric constant.. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant.Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly urea to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parametersincreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and polyethyl urethane to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, *In silico*, Polyvinyl Alcohol, Polyethyl urethane composite

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance

flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementations composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by do pant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy process ability [10]. On the other hand, PVA is non-toxic, semi-crystalline, hydrophilic, biocompatible, excellent water soluble and better film forming ability [11].

However, the polyethylurethane polymers were chosen as drug carriers for α-tocopherol. This active ingredient is widely used as a strong antioxidant in many potential applications including medical and cosmetic, but is rapidly degraded, because of its light, heat and oxygen sensitivity [12]. This study is intended to identify the interaction of polyvinyl alcohol and poly ethyl urethane to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyethyl urethane were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyethyl urethane as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of

group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of polyethyl urethane.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of polyethyl urethane.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the mebrane. Figure 3 show that the permeability of oxygenthrough the composite decreases with increase in mass fraction of polyethyl urethane.

Figure 4 show that the permeability of nitrogenthrough the composite decreases with increase in mass fraction of acrylic acid. Figure 5 show that the permeability of carbon dioxidethrough the composite decreases with increase in mass fraction of acrylic acid. Thus the results indicated that an increase in acrylic acid fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyethyl urethane to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and Polyoxymethylene to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, *In silico*, Polyvinyl Alcohol, Polyoxy methylene composite

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol is a promising material [8, 9]. The film forming ability of polyvinyl alcohol is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, polyvinyl alcohol is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11]. Researchers have used Polyoxymethylene in combination with polyvinyl alcohol based materialsshows good permeability behaviour. The radiochemical degradation of a "polyoxymethylene homopolymer (POM)" was used to study the effects of molar mass changes in the crystalline structure [12-13]. The properties are intended to identify the interaction of polyvinyl alcohol and polyoxymethylene to form blends.

MATERIALS AND METHODS

Software Used: "Materials studio module of Biovia software (Dassault Systemes of France)" was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and Polyoxymethylene were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcoholon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polymerX as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in "Synthia" uses topological information about polymers in the predictive correlations. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of vinyl alcohol

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of vinyl alcohol

Permeability of gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium. Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of vinyl alcohol

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of vinyl alcohol. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and Polyoxy methylene to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of vinyl alcohol usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Generally blend is a mixture of more than one components and the desired property is its homogeneity. In this current article the composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results signify that all those parameters increased with increase in mass fraction of acrylic acid. This study will help the researchers for determining the pairs of component of blend without laboratory experiment performance which save materials, money as well as time.

Keywords: Blend, *In silico*, Polyacrylic Acid and Polyacrylonitrile Composite

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *In silico* approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Acrylic polymers shows wide range of applications in maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10]. Polyacrylic acid is used as a electrolyte soluble in aqueous media at neutral pH, good adsorbent, hydrophobic, biocompatible and used as electrolyte [11, 12]. Researchers have used "polyacrylonitrile (PAN)" is a carbon fiber precursor and is also used for activated carbon. This study is intended to identify the interaction of polyacrylic acid and polyacrylonitrile to form blends.

MATERIALS AND METHODS

Software Used: "Materials studio module of Biovia software (Dassault Systemes of France)" was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyacrylic acid and polyacrylonitrile were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acid on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and polyacrylonitrile as potential components of a composite was analyzed using "Biovia Materials Studio". BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed.

Heat capacity: Figure 1 shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of acrylic acid.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

Dielectric constant: Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

CONCLUSION

The possibility of use of polyacrylic acid and polyacrylonitrile to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This *In silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend may be a mixture of more than one component. The specified property of a mix is its homogeneity. The composition of polyacrylic acid and polyacrylochloride to supply desired mechanical properties of the blend was explored using Bio via Materials Studio. The mechanical properties of the composite were studied supported bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle fatigue fracture. The results indicated that the values of all the properties increased with increase in mass fraction of propanoic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: blend, polyacrylic acid, polyacrylochloride, mechanical properties

INTRODUCTION

Blends or composites are materials containing quite one component. The components don't lose their identity within the mixture. They combine and contribute to the property of the blend thereby improving the standard of the fabric. Development of one material with the specified property involves significant research and time. a mix utilizes the benefits of various materials, mix them to urge the specified property. Thus, a mix saves time to develop a replacement material thereby reducing the value of development of products with desired properties. Polymer blends are often made from two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the thanks to multi-functional materials. Polymers including carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] are reported to reinforce mechanical properties and water resistance. Researchers are performing on

fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; which will enhance flame retardancy without increasing the load [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency within the field of transportation [5]. There are applications of composites in structural Engineering thanks to high strength to weight ratio and resistance to corrosion. Thus, optical fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.Usually blends are prepared by trial and error method. Thus, it involves wastage of materials, time and money. Thus, researchers have focused on the utilization of in silico approach to develop new blends. Software (Materials Studio [7]) are wont to identify compatible pairs.Acrylic polymers have an honest kind of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid may be a polyelectrolyte soluble in aqueous media at neutral pH it's used for preparing hydrogels. it's not toxic and doesn't cause irritation [11].Researchers have used polyacrylochloride together with other materials to act as adsorbent [12]. Polyacrylochloride are reported to be utilized in Curtius reaction.This study is meant to spot the interaction of polyacrylic acid and polyacrylochloride to make blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the extent of interaction.

Methodology

The structures of polyacrylic acid and polyacrylochloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acid on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the utilization of polyacrylic acid and polyacrylochloride as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to gauge a good range of polymer properties. Group additive methods were used for several years to predict the properties of polymers also as small molecules. These methods are extremely fast and straightforward to use. Consequently, they're of greatest utility when a rapid estimate of a property is required without an in depth understanding of the atomistic interactions that produce thereto. However, the principal shortcoming of those methods is their dependence upon a database of group contributions. Thus, if a polymer contains a gaggle that the group contribution cannot be estimated, then the property of that polymer cannot be calculated.To overcome this limitation, the tactic implemented in Synthia uses topological information about polymers within the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties could also be predicted for any polymer composed of any combination of the subsequent nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk modulus: coefficient of elasticity is that the measure of the decrease in volume with a rise in pressure. Figure 1 shows that the majority modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

Shear modulus: It is defined because the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

Young's modulus: It is defined because the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

Poisson ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

Brittle fracture stress: Brittle Fracture is the abrupt, rapid cracking of a materialbelow stress where the material displayedpractically no sign of ductility or plastic degradation before the fracture happens. Figure 5 shows that the brittle fracture stress of the composite growths linearly with growth in mass fraction of acrylic acid.

CONCLUSIONS

The possibility of use of polyacrylic acid and polyacrylochloride to make a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with reference to mechanical properties. The mechanical properties of the composite were studied supported bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle fatigue fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. Usually components for a mix are identified experimentally. This in silico study will help determine components of a mix without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one components.The desired property of a blend is its homogeneity. The selection of polyacrylic acid and polybutylene isopthalate to form a miscible blend was explored using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at high temperature. Phase diagram indicated that a single phase can be obtained above 1000 K which was the critical temperature. The coordination number was found to be 8.51 +/- 0.05. The highest number of configurations with respect to energy level was found to be -1.4 kcal/mol. The phase separation might lead to its use as porous material to be used as adsorbent. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: blend, homogeneity, polyacrylic acid , polybutylene isopthalate, Biovia Materials Studio.

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working

on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10].

Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH. It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have found polybutylene isopthalate to be partially crystalline, during copolymerization and there was a lowering in the amount of crystallinity and a decrease of melting temperature with respect to pure homopolymers [12]. This study is intended to identify the interaction of polyacrylic acid and polybutylene isopthalate to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyacrylic acid and polybutylene isopthalate were prepared using the build menu of Materials Studio. The structure of the components was optimized using the components used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and polybutylene isopthalate was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and polybutylene isopthalate as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m – *Gibb's free energy of mixing*

ΔH_m = *Enthalpy of mixing*

ΔS_m = *Entropy of mixing*

T = *Absolute temperature*

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend suggested that there might be a possibility of a miscible blend at very high temperature.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).
Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature. Thus at high temperature there is a possibility to form a miscible blend. The result is in agreement with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 8.51 +/- 0.05.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 1000 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 1000 K).
b. Fragmented metastable regions existed between binodals and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations

with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.4 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was high for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy .The formation of nonhomogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSIONS

The possibility of use of polyacrylic acid and polybutylene isopthalate to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at high temperature. Phase diagram indicated that a single phase can be obtained above 1000 K. The coordination number was found to be 8.51 +/- 0.05. The maximum number of configurations with respect to energy level was found to be -1.4 kcal/mol. The phase separation might make it a porous material to be used as an adsorbent. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is always a composition of two or more components and it is desirable to have homogeneity in a blend. In this paper, we have tried to explore the compatibility of polyacrylic acid and poly12aDglucose to form a miscible blend using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, and mixing energy. The results indicated that the pair can have very good compatibility at low to high temperature without any phase separation. The coordination number was found to be 6.46 +/- 0.04. The highest number of configurations with respect to energy level was found to be -1.9 kcal/mol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: blend, Biovia Materials Studio, poly12a D glucose,

INTRODUCTION

Blends or composites are materials containing more than one component. The components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength

important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10].

Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12]. It has been found that biopolymer blends possess good thermal stability [13].This study is intended to identify the interaction of polyacrylic acid and poly12aDglucose to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyacrylic acid and poly12aDglucose were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and poly12aDglucose was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and poly12aDglucose as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where $\Delta G_m = Gibb's\ free\ energy\ of\ mixing$

$\Delta H_m = Enthalpy\ of\ mixing$

$\Delta S_m = Entropy\ of\ mixing$

$T = Absolute\ temperature$

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always negative or less than zero for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will absolutely lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyacrylic acid and poly12aDglucose with negative value of mixing energy, which may lead to form a perfect blend with significantly less effort.

Chi Parameter

The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).Figure 2 shows that the χ value is very small or negative for the temperature range studied (50 to 500 K) indicating very good mixing. The χ value increased with an increase in temperature upto 250 K and the value decreased with further increase in temperature. There is a very good possibility of homogeneous mixing with such small value of χ which agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 6.46 +/- 0.04.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 3 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.9 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 4 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy. It also shows that mixing energy will be negative up to around 120 K, and the value gradually increases up to 0.6Kcal/Mol at a temperature of 270 K. However the mixing energy again reduces beyond the temperature 270 K. So, it is very much possible to mix the two components at any feasible temperature with least mixing energy value.The formation of nonhomogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSIONS

The possibility of use of polyacrylic acid and poly12aDglucose to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 6.46 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -1.9 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend may be a mixture of more than one component. The specified property of a mix is its homogeneity. The choice of polyacrylic acid and polyacrylochloride to make a miscible blend was explored using Bio via Materials Studio. The compatibility of the 2 components was studied supported free energy of blending, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at heat. Phase diagram indicated that one phase are often obtained above 750 K which was the critical temperature. The coordination number was found to be 5.59 0.04. The very best number of configurations with reference to energy state was found to be -1.6 kcal/mol. The phase separation might cause its use as porous material to be used as adsorbent. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: blend, Bio via Materials Studio, polyacrylochloride, homogeneity

INTRODUCTION

Blends or composites are materials containing quite one component. The components don't lose their identity within the mixture. They combine and contribute to the property of the blend thereby improving the standard of the fabric. Development of one material with the specified property involves significant research and time. a mix utilizes the benefits of various materials, mix them to urge the specified property. Thus, a mix saves time to develop a replacement material thereby reducing the value of development of products with desired properties. Polymer blends are often made from two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the thanks to multi-functional materials. Polymers including carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] are reported to reinforce mechanical properties and water resistance. Researchers are performing on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; which will enhance flame retardancy without increasing the load [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency within the field of transportation [5]. There are applications of composites in structural Engineering thanks to high strength to weight ratio and resistance to corrosion. Thus, optical fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.Usually blends are prepared by trial and error method. Thus, it involves wastage of materials, time and money. Thus, researchers have focused on the utilization of in silico approach to develop new blends. Software (Materials Studio [7]) are wont to identify compatible pairs. Acrylic polymers have a good sort of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid may be a polyelectrolyte soluble in aqueous media at neutral pH it's used for preparing hydrogels. it's not toxic and doesn't cause irritation [11]. Researchers have used polyacrylochloride together with other materials to act as adsorbent [12]. Polyacrylochloride are reported to be utilized in Curtius reaction. This study is meant to spot the interaction of polyacrylic acid and polyacrylochloride to make blend.

MATERIALS AND METHODS

Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyacrylic acid and polyacrylochloride were prepared using the build menu of Materials Studio. The structure of the components was optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and polyacrylochloride was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and polyacrylochloride as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where $\Delta G_m = Gibb's free energy of mixing$

$\Delta H_m = Enthalpy of mixing$

$\Delta S_m = Entropy of mixing$

$T = Absolute temperature$

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always positive for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend suggested that there might be a possibility of a miscible blend at very high temperature.

Chi Parameter: The Flory–Huggins χ parameter describes the surplus free energy of blending and helps to elucidate phase behavior for polymer blends and block copolymers. For polymers which aren't chemically similar, a big mismatch in cohesive energy density results in a high χ value and, hence, a greater drive for phase separation. Thus, a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymers having small cohesive energy difference χ value is predicted to be small. However, there's an opportunity of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them during a mixture from occupying an equivalent configuration experienced within the pure phase. Polymer theory can predict that a mismatch in chain stiffness for chemically similar components may cause a high positive value of χ (chi).Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature. Thus, at heat there's an opportunity to make a miscible blend. The result's in agreement with the free energy of blending for the blend.

Coordination Number : The coordination number Zij is that the number of molecules of type j which will be packed around one molecule of type I. The coordination number was calculated for every of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules aren't arranged on a daily lattice needless to say within the original Flory-Huggins theory. The coordination number is critical only the components of the binary blend have similar volumes or surface areas. it's difficult to use the pairs method in defining a coordination number for a binary numeration system during which the components aren't similar in size. During this study the coordination number was found to be 5.59 0.04.

Phase Diagram_: The compatibility of binary mixtures is often visualized by phase diagrams. Figure 3 shows the phase diagram for the 2 components of the blend. There are three regions of various degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 750 K. This value supported the very fact that one phase blend is often formed at a heat (higher than 750 K).
b. Fragmented metastable regions existed between binodal and spinodal, and
c. The two-phase separated regions of immiscibility are bordered by the spinodal.

The binodal separated miscible (one-phase) and metastable region, while the spinodal separated the metastable and two-phase region.When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e., slow nucleation followed by growth of the phase separated domains. On the opposite hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend : The generation of various orientations using the pairs method may cause configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there's an extended, low-energy tail. The number of configurations with energy above the height value decreased significantly. The utmost frequency was observed for the energy state of around -1.6 kcal/mol.

Mixing Energy: A little value of blending energy can favor the blending process. Thus, the temperature at which the blending energy is low is often chosen for mixing. Figure 5 shows that the blending energy for the system was high for the temperature range studied. The graph indicated that a rise in temperature helped reduce the blending energy. This result supported the previous observations.The formation of nonhomogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSIONS

The possibility of use of polyacrylic acid and polyacrylochloride to make a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed supported free energy of blending, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at heat. Phase diagram indicated that one phase is often obtained above 750 K. The coordination number was found to be 5.59 0.04. the utmost number of configurations with reference to energy state was found to be -1.6 kcal/mol. The phase separation might make it a porous material to be used as an adsorbent. Usually components for a mix are identified experimentally. This in silico study will help determine components of a mix without performing laboratory experiments saving materials, money and time.

ABSTRACT

Chemical blending and chemical mixing are chemical processes which create a new chemical by combining two or more different raw materials. During mixing chemicals it is always desired to get a homogenous new material. The selection of polyacrylic acid and polyacrylonitrile to form a miscible blend was explored using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at high temperature. Phase diagram indicated that a single phase can be obtained above 1000 K which was the critical temperature. The coordination number was found to be 5.38 +/- 0.04. The highest number of configurations with respect to energy level was found to be -1.8 kcal/mol. The phase separation might lead to its use as porous material to be used as adsorbent. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working

on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH. It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have found that poly acrylonitrile is thermoplastic and it does not melt under normal conditions, since it degrades before melting at above 300 °C [12]. Polyacrylonitrile also possesses a plasticizing effect on acrylic polymer and blocks the polar interactions between nitrile groups, and causes a lowering of melting point [13]. This study is intended to identify the interaction of polyacrylic acid and polyacrylonitrile to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyacrylic acid and Poly acrylonitrile were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and Poly acrylonitrile was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and Poly acrylonitrile as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = *Gibb's free energy of mixing*

ΔH_m = *Enthalpy of mixing*

ΔS_m = *Entropy of mixing*

T = *Absolute temperature*

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive with very small values for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). However the graph indicated that a slight increase in temperature above 500 K might help formation of a homogeneous mixture.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K, excluding 210-260 K) indicating demixing. The χ value was significantly small at the temperature 210 to 260 K , enhancing a possibility of forming a somewhat miscible blend at this temperature.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 5.38 +/- 0.04.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 800 K and also at a temperature between 200 K to 300 K with a very less value of mole fraction (0 to 0.07) and also at a very high mole fraction value of polyacrylonitrile beyond 0.94. This value supported the fact that single phase blend can be formed at different temperatures with specific mole fraction value.
b. Fragmented metastable regions existed between binodals and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat a symmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.6 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was high for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy. The formation of nonhomogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent/absorbent.

CONCLUSIONS

The possibility of use of polyacrylic acid and polyacrylonitrile to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at high temperature. Phase diagram indicated that a single phase can be obtained above 750 K as well as around 200 K depending on the mole fraction. The coordination number was found to be 5.59 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -1.6 kcal/mol. The phase separation might make it a porous material to be used as an adsorbent. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have used polymethylacrylate in combination with other materials such as SiO_2 to increase the thermal stability [12]. Polymethylacrylate has been reported to be used as solid state fluorescent material [13].This study is intended to identify the interaction of polyacrylic acid and polymethylacrylate to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyacrylic acid and polymethylacrylate were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and polymethyl acrylate was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and polymethylacrylate as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = Gibb's free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = *Entropy of mixing*

T = *Absolute temperature*

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend suggested that there might be a possibility of a miscible blend at very high temperature.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature. Thus at high temperature there is a possibility to form a miscible blend. The result is in agreement with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 5.24 +/- 0.04.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 2200 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 2200 K).
b. Fragmented metastable regions existed between binodals and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.4 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was high for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy. Figure 5 shows that mixing energy will be less up to around 300K. Thus, it is possible to mix the two components at this temperature. However, the phase diagram suggests that there will be phase separation.The formation of nonhomogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSIONS

The possibility of use of polyacrylic acid and polymethyl acrylate to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at high temperature. Phase diagram indicated that a single phase can be obtained above 2200 K. The coordination number was found to be 5.24 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -2.4 kcal/mol. The phase separation might make it a porous material to be used as an adsorbent. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and polyvinylchloride to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the compositewere studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: In silico analysis, blend, mechanical property, Biovia Materials Studio, polyvinyl alcohol.

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus; researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Polymerization of monomers containing vinyl group leads to the formation of vinyl polymers such as polyvinyl chloride [8], poly styrene [9], polyvinyl esters [10], polyvinyl acetate [11, 12] etc.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [13, 14]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [15]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [16].

Polyvinyl Chloride (PVC or Vinyl) is a high strength thermoplastic material having wide applications in the manufacture of pipes, medical devices, wire and cable insulation the list is endless. It is the world's third-most widely produced synthetic plastic polymer for its superior mechanical and physical properties. However, the fluid plasticity and thermal stability of PVC are inferior to those of other commodity plastics such as polyethylene and polystyrene [17]. Much work on improvement of the inferior properties of PVC has been carried out besides the addition of additives such as plasticizers, heat stabilizers, lubricants, fillers and other polymers [18]. This study is intended to identify the interaction of polyvinyl alcohol and polyvinyl chloride to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of polyvinyl alcohol and polyvinyl chloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS & DISCUSSION

In this work the use of polyvinyl alcohol and polyvinyl chloride as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group contribution methods are being used for several years to estimate the properties of polymers and other small molecules. These techniques have the advantages of quick calculation, user friendly approach and do not need any specialized

knowledge.As a result of this, these methods are well accepted and vastly used to predict the properties of range of molecules and polymers. However, the fundamental limitation of this group contribution method lies over the fact that it needs a strong set of database of group contribution based on which it could predict the desired properties.Therefore, if a polymer contains certain groups whose group contribution values have not been assigned, then it is difficult to predict the property of that polymer.

Synthia adopt a different approach to overcome the group contribution limitation wherein topological information was utilized to predict the properties.The connectivity indices derived from graph theory are employedand the database of group contribution is not necessary to predict the properties. Therefore, the polymer properties could be estimated for any kind of polymer that composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. As can be seen from Figure 1, there is a rise in the bulk modulus of the composite upon increasing the mass fraction of the vinyl alcohol.

Shear modulus: It is one of the ways in measuring the stiffness of the polymer composite. It shows the responseof the composite to shear deformation. As depicted in Figure 2, upon increasing the mass fraction of vinyl alcohol, the shear modulus of the composite increases linearly.

Young's modulus: In the linear elasticity region, young's modulus is the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that upon increasing the mass fraction of vinyl alcohol, the Young's modulus of the composite increases linearly.

Poisson ratio: It is defined as the ratio of transverse strain to axial strain. As illustrated in Figure 4, Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle fracture stress: This is an unstable process where fracture in the material takes place even before any plastic degradation. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyvinyl chloride to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

This article provides the theoretical information of a blendof two monomers with varying mass fraction concerning their gas permeability properties. Blend is a mixture of more than one component. The desired property of a blend is its homogeneity, perhaps it may be heterogeneous.Vinyl alcohol and 1,2-α-D-glucosemonomers are considered to be the indivisual components to get the desired mechanical properties of the blend. This study is explored using Biovia Materials Studio synthia analysis. The permeability properties of the polymer composite were analyzed concerning with varying mass fraction of components. The molar volume and density decreased with an increase in vinyl alcoholmass fraction. The permeability properties of the composite were studied based on the permeability of oxygen, nitrogen, and carbon dioxide. The results showed that the permeability of all the gases decreased with the increase in the mass fraction of vinyl alcohol. This study will help to determine pairs without performing laboratory experiments, saving materials, money, and time.

Keywords: Synthia, in silico, polyvinyl alcohol, poly-1, 2-α-D-glucose, biovia material studio, gas permeability

INTRODUCTION

Blends or composites are the physical combination of more than one component where components do retain their identity in the mixture. The blend may be a homogenous or heterogeneous mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process which provides an easy pathway develop a new material by reducing the cost of development of products with

preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.A composite/blend possess significantly different chemical andphysical characteristics from those of its constituent components. In a composite the constituents remain physically separable and distinct from each other. Usually, a composite is a matrix in which strong and stiff reinforcement is distributed but made of a soft and weaker component [1-3].The upgraded properties of composites are predominantly governed by their microstructure and interaction between matrix and reinforcing materials in the inter-phase region [4, 5].Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [6] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [7] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [8]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [9].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [10]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [11] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [12]) has been used to identify compatible pairs. Polyvinyl alcohol (PVA) is a promising material among several polymers that have high dielectric strength, easy film formation, and adhesiveness. These properties can be modified by dopant concentrations [13, 14]. Moreover, due to their high mechanical strength, environmental stability, easy processability, and film forming ability, PVA is usually used in packaging industry to form strong polymeric films [15]. In addition, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [16].

Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [17]. It has been found that biopolymer blends possess good thermal stability [18].By adding glycopolymers (cellulose nanoscale fillers) in different polymers (polyvinyl alcohol or polylactic acid) we can generate nanocomposites resulting in mechanical reinforcement and alternation of other properties [19].This study is intended to identify the interaction of polyvinyl alcohol and poly-1, 2-α-D-glucose to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of polyvinyl alcohol and poly-1, 2-α-D-glucose were fed to the synthia menu of Materials Studio. It was then run for different mass fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of mass fraction of polyvinyl alcohol on the mechanical properties of the composite. The structures of poly vinyl alcohol and Poly Ethyl Urethane were fed to the

synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of poly vinyl alcoholon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work, the use of polyvinyl alcohol and poly-1, 2-α-D-glucose as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties.From several years, group additive methods are used to estimate the properties of polymers and other molecules. These methods are quick and can be used easily that eventually leads to wide utilization to estimate the properties of materials. Moreover, these techniques do not require any specific expertise and the values from database are extracted that each group could contribute for a specific property. Finally, the values for each group are added that makes up the material/composite. However, the primary limitation that exist with these methods lies with the fact that, the property of a material may not be determined if the group contribution value is not available for a particular group that makes up the molecule.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases with an increase in the mass fraction of vinyl alcohol.

Density: Decrease in density indicates increase in the porosity. A higher porosity will enhance the surface area making it suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in the mass fraction of vinyl alcohol.

Permeability of gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates a longer time lag for the gas to pass through the membrane. Figure 3 show that the permeability of oxygenthrough the composite decreases with increase in the mass fraction of vinyl alcohol.

Figure 4 show that the permeability of nitrogenthrough the composite decreases with increase in mass fraction of vinyl alcohol. Figure 5 show that the permeability of carbon dioxidethrough the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influenced by the molecular weight of the gases. The decrease in the permeability of the gases makes the composite suitable for the development of packaging materials.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1,2-α-D-glucose to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties of different gases like Oxygen, Nitrogen, and carbon dioxide.The molar volume and density decreased with an increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on the permeability of

oxygen, nitrogen, and carbon dioxide. The results indicated that the permeabilityof all the gases decreased with the increase in the mass fraction of vinyl alcohol. Usually, components of a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments, saving materials, money, and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl lalcohol and polyvinylchloride to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: In silico analysis, gas permeability, polyvinyl alcohol, blend, Biovia Materials Studio.

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Polymerization of monomers containing vinyl group leads to the formation of vinyl polymers such as polyvinyl chloride [8], poly styrene [9], polyvinyl esters[10], polyvinyl acetate[11, 12] etc.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [13, 14]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [15]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [16].

Polyvinyl Chloride (PVC or Vinyl) is a high strength thermoplastic material having wide applications in the manufacture of pipes, medical devices, wire and cable insulation...the list is endless. It is the world's third-most widely produced synthetic plastic polymer for its superior mechanical and physical properties. However the fluid plasticity and thermal stability of PVC areinferior to those of other commodity plastics such as polyethylene and polystyrene [17]. Much work on improvement of the inferior properties of PVC has been carried out besides the addition of additives such as plasticizers, heat stabilizers, lubricants, fillers and other polymers [18].This study is intended to identify the interaction of polyvinyl alcohol and polyvinyl chloride to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of polyvinylalcohol and polyvinyl chloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinylalcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyavinyl chloride as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. From several years, group additive methods are used to estimate the properties of polymers and small molecules as well. The wide application of these methods is due to their user-friendliness and fastness in calculations. Furthermore, these techniques do not require in depth knowledge of intermolecular interactions to predict the properties and it solely

depends upon the database containing the group contribution values. However, the primary limitation with these techniques lies with the fact that, for a new material/polymer that constitutes new groups, the group additive methods may not determine the properties as there will be no data for the new groups in the database. To overcome this limitation, topological information was utilized in Synthia to estimate the properties of polymers. The connectivity indices derived from the graph theory are employed to predict the properties rather than using the group contribution values from the database. Therefore, properties of the polymers that composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine can be determined using Synthia.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Permeability of gas: Permeability determines the speed at which the gas can pass through the polymer membrane after it is accumulated in the higher potential side of the membrane.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygenthroughthe composite decreases with increase in mass fraction of vinyl alcohol.

Figure 4 show that the permeability of nitrogenthrough the composite decreases with increase in mass fraction of vinyl alcohol. Figure 5 show that the permeability of carbon dioxidethrough the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyvinyl chloride to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Hybrid polymers with improved gas barrier properties are the major concern of packaging application. As blends are the selective combination of two or more polymeric components to get the desired one with low cost, it can be more easily adopted for mass production. The optimum blend composition of poly (biphenyl dimethylcarbonate)and polyether sulfone (PES) to provide the desired gas barrier properties was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties towards various gases. The molar volume was found to be increased, while density was decreased with increase in the mass fraction of poly(biphenyl dimethylcarbonate) (PC). The permeability properties of the blend were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases increases with increase in mass fraction of poly (biphenyl dimethyl carbonate). This study will help determine pairs without performing laboratory experiments saving materials, money and time

Keywords: Gas permeability, Hybrid, In-silico analysis, Compatibility, Packaging

INTRODUCTION

Polymeric blends are usually offered improved physical and chemical properties like thermal, mechanical, gas barrier and biodegradability [1]. These properties are the prime interest for the researchers to design best packaging material. Gas permeability is sometimes offered as essential criterion to design the polymer for biomedical and industrial utilization. For instance, polymers with high barrier properties, i.e. low permeability, are mandatory for food packaging applications to prevent loss of aroma, color and food-value and to slow down spoilage [2]. Apart from this food packaging application; there are lots of other applications which require the polymers to have high, low or tailored permeability like, filters and membranes for gas or liquid separation [3], protective coatings (e.g., paints and varnishes) [4], polymer coatings for controlled drug release [5] and water desalination [6].The permeability of liquids and gases through polymer membranes (plastic films) may be happened by either a

temperature or pressure gradient, or by concentration gradient or external force field. The "solution-diffusion" mechanism is generally used to depict the pathway of gas permeation. It involvesthree steps. In the first step absorption of small molecules is happened into the membrane at the side of higher gradient (concentration, pressure, etc). On the other hand, second step involves the molecular diffusion through the membrane and the final step is related to desorption of those molecules from the membrane at the opposite side of lower gradient. The gas permeability in a polymer is generally varied with the nature of polymer and permeates. It may be accounted due to various degree of crystallinity and porosity of the polymers along with surface functionality (hydrophilic/ hydrophobic groups).The main aim of combining polymeric materials is to achieve the desired quality of the material. Among various polymers, polybiphenyldimethyl carbonate (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical strength[7]. As a resultof these excellent properties, PC has been largely employed in electronic and electronic appliances along with automotive industry, having an annual production of 6 million tons.

Recent report by Behboudi et. al. [8] shows thatPC is blended withpolyvinyl chloride (PVC)to preparethe ultrafiltration membrane for water purification. On the other hand, PC is also blended with poly(vinylidene fluoride) (PVDF) to prepare mechanically strong multicomponent nano composites with nano structural reinforcement of graphene nanoplates, carbon nanotube, and organically modified montmorillonite [9]. In another recent report Wen et al. reinforced the graphene plates into blend of polybutyleneterethalate and polycarbonate [10] to obtain electrical and thermal conductive materials. The unique material, formed from the blend of PC with polystyrene is also reported to sense organic vapours with incorporation of multiwalled carbon nanotubes (MWCNTs) [11]. Polycarbonate blended polysulfone material is recently observed to have improved thermal and mechanical properties [12]. Therefore, investigation of blending compatibility of polycarbonate with other polymer is the urgent need of current research to develop advanced functional materials. All the above mentioned examples relied on laboratory experiments. Usually, preparation of homogeneous blend in wet-lab condition, requires huge time and wastage of materials which can be minimized by in-silico approach through material studio [13] of "Biovia" software.. In present context, we are focusing to optimize the homogeneous blend composition of polybiphrnyldimethylcarbonate (PC) with polyether sulfone (PES) in terms of gas permeability. Among various engineering polymers, polyether sulfone (PES) is a high-temperature sustaining thermoplastic polymer with striking strength and chemical stability from various organic solvents. It belongs to the polysulfone family and contains an aryl-SO_2 subunit in their long chain structures. Nonetheless, the inherent hydrophobic property of PES makes this material sensitive to membrane fouling, restricting its more extensive applications in membrane based water treatment. Due to high chemical stability it is also preferably used for gas separation in harsh environment.

To improve the gas separation efficiency of PES, a few investigations have been performed. In a report, Adib et al. [14] incorporated the nanostructural silica to improve the gas separation. However, blending of PES with other hydrophilic polymer is one of the easiest routes to improve the efficiency of the gas separation. In another report, Mannan et al. [15] investigated the gas-permeation behavior of glassy poly(vinyl acetate) (PVAc)–PES hybrid films and PSF–PES film. Interestingly, it is found that the gas permeation properties of hybrid PSF–PES film is remain unaltered as compared to the properties of polyether sulfone. However on account of the PES–PVAc hybrid polymer, low selectivity was observed for gas separation and may be accounted as the phase separation in their blend. Kamal et al. [16] revealed that the blend with elastomers (like polydimethylsiloxane) leads to the improved gas permeation properties of the polydimethylsiloxane–PES hybrid. Akbarian et al.[17] prepared the PES based blend membranes for CO_2 gas separation with inclusion polyethylene glycol (PEG) as second polymer.Therefore, the present in-silico approach of blend analysis between poly(biphenyl dimethyl carbonate) (PC) and polyether sulfone (PES) may be utilized to optimize the composition to fabricate desirable functional materials with some improved physical and chemical properties.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of poly (biphenyl dimethylcarbonate) and polyether sulfone (PES) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of Poly(biphenyl dimethylcarbonate) on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly(biphenyl dimethylcarbonate)and polyether sulfone as potential components of a blend was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the blend hybrid increasedlinearly with increase in mass fraction of biphenyl dimethyl carbonate.

Density: Decrease in density indicates the enhancement of porous morphology. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows the density variation of the blend which showed a linear decrease with increase in mass fraction of biphenyl dimethyl carbonate. This decrease in density along with increase of molar volume indicates the phase separation of individual polymeric components and therefore, creating porous morphology.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3shows that the permeability of oxygenthrough the blend hybrid increasedwith increase in mass fraction of biphenyl dimethyl carbonate. On the other hand, Figure 4 shows that the permeability of nitrogenthrough the hybrid blend increasedwith increase in mass fraction of biphenyl dimethyl carbonate. In the same analogy and as expected, Figure 5shows that the permeability of carbon dioxidethrough the blend hybrid increased with increase in mass fraction of biphenyl dimethyl carbonate.

Thus the results indicated that an increase in biphenyl dimethyl carbonate fraction increased the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of poly (biphenyl dimethylcarbonate) and polyethersulfoneto form aadvanced adsorbent material was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume increased, while density decreased with increase in biphenyl dimethyl carbonate fraction due to formation of porous morphology. The permeability properties of the blend hybrid were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases increased with increase in mass fraction of biphenyl dimethyl carbonate. Usually components for a blend are identified experimentally. This in-silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Polymeric blends are useful in preparing hybrid materials with improved properties, related to packaging application. Blends are basically prepared with two or more than two polymers. The improvements in physical and chemical property of these blends are strongly depicted through their molecular level of interactions and therefore, guided by their mixing compatibility or homogeneity of the blends. To get the desired mechanical and gas barrier performance of the prepared polybiphenyldimethyl carbonate (PC) based packaging material, the optimum composition of PC with polydimethylsiloxane (PDMS) was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density was found to increase with the increase in poly (biphenyl dimethylcarbonate) fraction or lowing of polydimethylsiloxane fraction. The permeability properties of the blend were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of biphenyl dimethyl carbonate. This in-silicostudy helps us to determine the best composition of the blend without performing laboratory experiments which saves valuable time and wastage of raw materials too.

Keywords: Gas permeability, Blend, in-silico analysis, Compatibility, Packaging

INTRODUCTION

Polymeric blends are usually offered improved physical and chemical properties like thermal, mechanical, gas barrier and biodegradability [1]. These properties are the prime interest for the researchers to design best packaging

material. Gas permeability is sometimes offered as essential criterion to design the polymer for biomedical and industrial utilization. For instance, polymers with high barrier properties, i.e. low permeability, are mandatory for food packaging applications to prevent loss of aroma, color and food-value and to slow down spoilage [2]. Apart from this food packaging application; there are lots of other applications which require the polymers to have high, low or tailored permeability like, filters and membranes for gas or liquid separation [3], protective coatings (e.g., paints and varnishes) [4], polymer coatings for controlled drug release [5] and water desalination [6].The permeability of liquids and gases through polymer membranes (plastic films) may be happened by either a temperature or pressure gradient, or by concentration gradient or external force field. The ''solution-diffusion'' mechanism is generally used to depict the pathway of gas permeation. It involvesthree steps. In the first step absorption of small molecules is happened into the membrane at the side of higher gradient (concentration, pressure, etc). On the other hand, second step involves the molecular diffusion through the membrane and the final step is related to desorption of those molecules from the membrane at the opposite side of lower gradient. The gas permeability in a polymer is generally varied with the nature of polymer and permeates. It may be accounted due to various degree of crystallinityand porosity of the polymers along with surface functionality (hydrophilic/ hydrophobic groups).

The main aim of combining polymeric materials is to achieve the desired quality of the material. Among various polymers, polybiphenyldimethylcarbonate (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical strength[7]. As a resultof these excellent properties, PC has been largely employed in electronic and electronic appliances along with automotive industry, having an annual production of 6 million tons. Recent report by Behboudi et. al. [8] shows thatPC is blended withpolyvinyl chloride (PVC)to preparethe ultrafiltration membrane for water purification. On the other hand, PC is also blended with poly(vinylidene fluoride) (PVDF) to prepare mechanically strong multicomponent nanocomposites with nanostructural reinforcement of graphenenanoplates, carbon nanotube, and organically modified montmorillonite [9]. In another recent report Wen et al. reinforced the graphene plates into blend of polybutyleneterethalate and polycarbonate [10] to obtain electrical and thermal conductive materials. The unique material, formed from the blend of PC with polystyrene is also reported to sense organic vapours with incorporation of multiwalled carbon nanotubes (MWCNTs) [11]. Polycarbonate blended polysulfone material is recently observed to have improved thermal and mechanical properties[12].

Therefore, investigation of blending compatibility of polycarbonate with other polymer is the urgent need of current research to develop advanced functional materials. All the above mentioned examples relied on laboratory experiments. Usually, preparation of homogeneous blend in wet-lab condition requires huge time and wastage of materials which can be minimized by in-silico approach through material studio [13] of "Biovia" software. In present context, we are focusing to optimize the homogeneous blend composition of poly (biphrnyl dimethylcarbonate) (PC) with polydimethylsiloxane (PDMS) in terms of gas permeability. Polydimethylsiloxane is a polymeric organosilicon compound, especially known for its unordinary rheological practices. Also it is optically clear, non-harmful and non-combustible. Polydimethylsiloxane (PDMS) shows wide applications like contact focal points, clinical gadgets and advanced elastomer materials. It is likewise utilized in creation of ointments and heat-resistant tiles. As of late, Adrees et. al. [14] prepared the PDMS based mixed layers with polyvinyl chloride-co-vinyl acetic acid derivative (PVCA) for CO_2seperation. Polydimethylsiloxane is likewise utilized in biomedical application like maxillofacial prosthetics, fake veins and articular ligament substitution, when it is mixed with poly (ether) ketone (PEEK) [15]. Consequently, the present in-silico approach towards examination of gas permeability of the blend having various composition of poly (biphenyldimethyl carbonate) (PC) and polydimethylsiloxane (PDMS) might be used to upgrade the sythesis to create attractive advanced materials for packaging applications.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction

Methodology

The structures of poly (biphenyl dimethylcarbonate) and polydimethylsiloxane (PDMS) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of poly (biphenyl dimethylcarbonate) on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly(biphenyl dimethylcarbonate)and polydimethylsiloxaneas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite increasedlinearly with increase in mass fraction of biphenyl dimethyl carbonate.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite increased linearly with increase in mass fraction of biphenyl dimethyl carbonates. Therefore, prepared materials offered compact structures which may not be suitable for adsorption, but suitable for packaging material, where high gas barrier property is required

Permeability of gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygenthrough the hybrid polymer decreased with increase in mass fraction of biphenyl dimethyl carbonate.

On the other hand, Figure 4 shows that the permeability of nitrogenthrough the hybrid polymer is decreased with increase in mass fraction of biphenyl dimethyl carbonate.Thus the results indicated that an increase in biphenyl dimethyl carbonate fraction reduced the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of poly (biphenyl dimethylcarbonate) and polydimethylsiloxaneto form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume and density decreased with increase in biphenyl dimethyl carbonate fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of biphenyl dimethyl carbonate. Usually components for a blend are identified experimentally. This in-silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is formed from the combination of two or more components. The change in properties of polyvinyl alcohol and poly-1, 2-α-D-galactose was studied to form a miscible blend using Biovia Materials Studio. The permeability properties of composition of the blend were studied so that it can be used in different potential application. The molar volume and density of the blend was observed to be decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were observed based on permeability of various gases such as: carbon dioxide, nitrogen and oxygen. From analysis of results, it was noticed that the permeability property of these gases is decreased with increase in mass fraction of vinyl alcohol. This technique will be useful us to determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend; Biovia Material Studio; Gas permeability properties; Polyvinyl alcohol; In silico analysis

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is incredibly tough to seek out multiple properties during a single material, it's suggested to mix totally different component thereby enhancing the properties of the material. Development of one material with the required property involves important analysis and time. A blend uses the upsides of various materials; blend them to get the ideal property. In this manner a blend spares time to build up a new material along with decreasing the cost of advancement of products with wanted properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers combined with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber

composites [2] have been accounted for to upgrade mechanical properties and water resistance. Researchers have given attention on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can improve fire retardancy without expanding the weight [4]. Scientists have accentuated on synthesis and production of lightweight composite materials having high quality significant for upgrading fuel efficiency in the field of transportation [5]. There are uses of composites in structural Engineering because of high strength to weight proportion and resistance to corrosion. Consequently, glass fiber incorporated polymers, latex polymer cementations composites [6] were created for development of construction of bridges, light rail transit, mining and tunneling, holding dividers and other waterside buildings. All the previously mentioned models depended on research center analyses.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Among different polymeric materials, polyvinyl alcohol (PVA) is one of the highly demanding material because of its robust and amicable properties such as: high dielectric nature, easy film formation ability, and adhesiveness properties. Moreover, the properties such material can be easily controlled according to requirement by altering the concentration of dopant [8, 9]. In the recent years, taking the advantages of PVA, many of the polymeric industry are inclined to produce strong polymeric films. These amicable properties of PAV have resulted in the formation of high mechanical strength and easy processability material [10]. In addition to that PAV is potentially non-toxic, biocompatible and easily soluble in water [11].

Researchers have used D-galactose in combination with other materials to different applications [12]. Poly-1, 2-α-D-galactose has been reported to be used in Curtius reaction. This study is intended to find out the change of gas permeability value of blend of polyvinyl alcohol and poly-1, 2-α-D-galactose with different proportions.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of polyvinyl alcohol and poly-1, 2-α-D-galactose were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1, 2-α-D-galactose as potential components of a composite was analyzed using Biovia Materials Studio. This computational tool uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate polymeric properties of materials. Furthermore, there are various computational methods belong to Group additive methods were extensively used from last few decades to determine the properties of polymer and small molecules. These computational methods are quite fast and pretty simple to use. Owing to these advantages, they have a great demand for rapid estimation of properties in critical condition without detailed understanding of the atomistic interactions. However, the principal shortcoming of these

methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium. Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of vinyl alcohol.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of vinyl alcohol. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1, 2-α-D-galactose to form a homogeneous blend was explored using Biovia Materials Studio. The molar volume, density and permeability of different gases such as oxygen, nitrogen and carbon dioxide were demonstrated using Biovia Materials Studio. From the results it was found that the molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composites were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of vinyl alcohol. Due to decrease in gas permeability value, the blend can be used in different practical application. Usually components for a blend are identified experimentally. This in silico study will help to determine components of a blend without doing experiments in laboratory.

ABSTRACT

The present work deals with the in silico information for mechanical properties of blend. These properties were determined by variation of polyvinyl alcohol and poly-1, 2-α-D-glucose compositions using Biovia, Materials Studio, Synthia analysis.Based on sheer, bulk, and Young's modulus and Poisson ratio, brittle stress fracture, the mechanical properties were determined.The results indicated that the values of bulk modulus, shear modulus, Young' modulus decreased with an increase in the mass fraction of vinyl alcohol whereas the Poisson ratio, and brittle stress fracture decrease. Usually, components for a blend are identified experimentally. This study will help determine pairs without performing laboratory experiments saving materials, money, and time.

Keywords: Synthia, in silico, polyvinyl alcohol, poly-1, 2-α-D-glucose, biovia material studio, mechanical property.

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture. Blends or composites are the physical combinations of more than one component where components do retain their identity in the mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process that provides an easy pathway to develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. The chemical and physical characteristics of a composite or blend are different from its constituents. Composites, usually are, matrices in which the distribution of reinforcement (strong/stiffness) is uniform [1-3]. The greater properties of composites are mainly due to their microstructure and interaction between the matrix and filler. [4, 5]. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [6]

have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [7] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [8]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [9]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [10]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [11] were developed for the construction of bridges, light rail transit, mining, and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.

Usually, blends are prepared by trial and error method and this technique is a low cost and less time-consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [12]) has been used to identify compatible pairs. The Polyvinyl alcohol (PVA) is a promishing material among various polymers, which is because of its easy film formation, high dielectric strength, good adhesiveness. These properties can be controlled by controlling the dopant concentration [13, 14]. The packaging industry widely uses the film forming ability of PVA forming strong film, which is because of environmental stability, greater mechanical strength , and easy processability [15]. In addition, PVA is non-toxic, hydrophilic, semicrystalline, easily soluble in water and biocompatible [16].

Different research groups have found applicability of glycopolymers (synthetic polymers containing pendant carbohydrate groups) for th removal of toxic chemicals and bacteria [17] Also it is used in in tumor cell recognition, and glucose-responsive insulin delivery [17]. Moreover, biopolymer blends possess good thermal stability [18]. By adding glycopolymers (cellulose nanoscale fillers) in different polymers (polyvinyl alcohol or polylactic acid) we can generate nanocomposites resulting in mechanical reinforcement and alternation of other properties [19].This study is intended to identify the interaction of polyvinyl alcohol and poly-12-a-D-glucose to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

The structures of polyvinyl alcohol and poly-1, 2-α-D-glucosewerefed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work, the use of polyvinyl alcohol and poly-1, 2-α-D-glucose as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. For the prediction of the properties of the polymers, group additive methods have been used from many years. The extreme fastness of these methods and easy usability makes them useful. Also their utility is high when a ripid estimation of a property is required. Without details of atomistic interactions. However, the important drawback of such methods is their dependability upon a database comprising of group contribution. Thus, if a polymer contains a group for which the

group contribution cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite decreases linearly with an increase in mass fraction of vinyl alcohol.

Shear modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite decreases with increase in mass fraction of vinyl alcohol.

Young's modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that Young's modulus of the composite decreases with increase in mass fraction of vinyl alcohol.

Poisson ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases with increase in mass fraction of vinyl alcohol.

Brittle fracture stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of the use of polyvinyl alcohol and poly-1, 2-α-D-glucose to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed concerning mechanical properties. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio, and brittle stress fracture. The findings show that the bulk modulus, shear modulus, YHoung'sjmodulus decreases with mass fraction of vinyl alcohol. On the other hand the Poisson ratio and brittle stress fracture decreases. The results indicated that the values of bulk modulus, shear modulus, Young' modulus decreased with an increase in the mass fraction of vinyl alcohol whereas the Poisson ratio, and brittle stress fracture decrease. Usually, components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The selection of polyvinyl alcohol and polyvinylchloride to form a miscible blend was explored using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at and beyond 500K. Phase diagram indicated that a single phase can be obtained above 450 K which was the critical temperature. The coordination number was found to be 5.65 +/- 0.01. The highest number of configurations with respect to energy level was found to be -1.9 kcal/mol. The phase separation might lead to its use as porous material to be used as adsorbent. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: n silico analysis, blend, polyvinyl alcohol, phase diagram.

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance

flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus; researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Polymerization of monomers containing vinyl group leads to the formation of vinyl polymers such as polyvinyl chloride [8], poly styrene [9], polyvinyl esters[10], polyvinyl acetate[11, 12] etc. Polyvinyl alcohol (PVA) is a promising material among different polymers, because of its ability to form film easily, greater dielectric strength, good adhesiveness and also its properties can be tuned by concentration of dopant [13, 14]. Packaging industry widely uses the film forming ability of PVA, which is because of high mechanical strength, environmental stability and easy processability [15]. In addition, PVA hydrophilic, nontoxic, biocompatible and soluble in water [16].

Polyvinyl Chloride (PVC or Vinyl) find its applications in manufacture of medical devices, pipes, cable insulation, and wires and many others. It is known for superior mechanical and physical properties. However the fluid plasticity and thermal stability of PVC are inferior to those of other commodity plastics such as polyethylene and polystyrene [17]. Much work on improvement of the inferior properties of PVC has been carried out besides the addition of additives such as plasticizers, heat stabilizers, lubricants, fillers and other polymers [18]. This study is intended to identify the interaction of polyvinyl alcohol and polyvinyl chloride to form blends.

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyvinyl alcohol and polyvinylchloride were prepared using the build menu of Materials Studio. The structure of the components were optimized using The components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and polyvinylchloride was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend were analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyvinyl chloride as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = Gibb's free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = *Entropyofmixing*

T = *Absolutetemperature*

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is positive initially and then decreases gradually and attain even negative when the temperature moves from 50K to 500K. There is an exception seen in the phase diagram. When the temperature increased from 50K to 162.5K, the free energy of the process also increased which is against Eq. 1. Further increase in temperature decreased the free energy that supports Eq. 1. The result indicated that the blend will lead to a homogeneous mixture at and beyond 500K.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature. Thus at high temperature there is a possibility to form a miscible blend. The result is in agreement with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this study the coordination number was found to be5.65 +/- 0.01.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperatureof around 450 K. This value supported the fact that a single phase blend can be formed at a moderate temperature (higher than 450 K) which is in agreement with the conclusion drawn from the free energy of mixing.

b. Fragmented metastable regions existedbetween binodals and spinodals, and

c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.

When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains.

On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreasedsignificantly. The maximum frequency was observed for the energy level of around -1.9kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was high for the temperature range studied. The graph indicated that an increase in temperature helped reduce the mixing energy. This result supported the previous observations.

The formation of nonhomogeneous blend with polyvinyl alcohol as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyvinyl chloride to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at a temperature of 500K or more than that. Phase diagram indicated that a single phase can be obtained above 450 K. The coordination number was found to be 5.65 +/- 0.01. The maximum number of configurations with respect to energy level was found to be -1.9kcal/mol.The phase separation might make it a porous material to be used as an adsorbent. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blendis especially to combine or associate of more than one constituents or the line of demarcation cannot be distinguished. The desired property of a blend is its homogeneity. The selection of polyacrylic acid and polyurea to form a miscible blend was explored using Biovia Materials Studio. The compatibility of the two components was studied based on the free energy of mixing, chi parameter, phase diagram, and mixing energy. The results indicated that the pair can become compatible only at high temperatures. Phase diagram indicated that a single phase can be obtained above 750 K which was the critical temperature. The coordination number was found to be 5.36 +/- 0.04. The highest number of configurations concerning energy level was found to be -1.4 kcal/mol. The phase separation might lead to its use as porous material to be used as adsorbent. This study will help determine pairs without performing laboratory experiments saving materials, money, and time.

Keywords: Blend, in silico, polyacrylic acid,polyurea

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.Nanomaterial modified polymers paved the way for multifunctional materials. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame

retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials; time, and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects, etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10].

Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not irritate [11]. This study is intended to identify the interaction of polyacrylic acid and polyurea to form blends. Polyurea, which is a typical elastomer, is a reaction product of an isocyanate and a synthetic resin blend through polymerization step growth. The isocyanate can be monomer, polyhmer, aliphatic or aromatic. It can also be any variant reaction of of isocyanates, quasi-prepolymeror a prepolymer. The prepolymer /quasi-prepolymer may be a hydroxyl-terminated polymer or an amine-terminated [12].

MATERIALS AND METHODS

Software Used

Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology

Polyacrylic acid and polyurea were prepared using the build menu of Materials Studio. The structure of the components was optimized using the components that were used in the blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and polyurea was used as a screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and polyurea as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where $\Delta G_m = Gibb's\ free\ energy\ of\ mixing$

$\Delta H_m = Enthalpy\ of\ mixing$

$\Delta S_m = Entropy\ of\ mixing$

$T - Absolute\ temperature$

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always positive for the temperatures studied. The free energy decreases with an increase in temperature as evident from Eq. 1. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend suggested that there might be a possibility of a miscible blend at a very high temperature.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high for the temperature range studied (60 to 480 K) indicating demixing. The χ value decreased with an increase in temperature. Thus at high temperature there is a possibility to form a miscible blend. The result is in agreement with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules that are not arranged on a regular lattice is expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this study the coordination number was found to be 5.36 +/- 0.04.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:
a. The single-phase miscible region existed above the critical temperatureof around 750 K. This value supported the fact that a single-phase blend can be formed at a high temperature (higher than 750 K).
b. Fragmented metastable regions existedbetween binodal and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.
The binodal separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.When the system enters from a single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase-separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations

with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.4kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was high for the temperature range studied. The graph indicated that an increase in temperature helped reduce the mixing energy. This result supported the previous observations. The formation of a nonhomogeneous blend with polyacrylic acid as a base might help the formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSION

The possibility of the use of polyacrylic acid and polyurea to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on the free energy of mixing, chi parameter, phase diagram, and mixing energy. The results indicated that the pair can become compatible at high temperatures. Phase diagram indicated that a single phase can be obtained above 750 K. The coordination number was found to be 5.36 +/- 0.04. The maximum number of configurations concerningthe energy level was found to be -1.4 kcal/mol.The phase separation might make it a porous material to be used as an adsorbent. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The two parameters excluding heat capacity are found to be increasing but heat capacity itself decreased with the rise in the value of mass fraction of vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: In-silico analysis, polyvinyl chloride, thermal property, composite, dielectric property, polyvinyl alcohol

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio

and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

There exist different vinyl polymers which are formed by the polymerization of the monomers that contains vinyl groups. Some of these vinyl polymers are namely polyvinyl chloride [8], poly styrene [9], polyvinyl esters [10], polyvinyl acetate [11, 12] etc. Polyvinyl alcohol (PVA) has high dielectric strength, easy film formation and adhesiveness for which it is treated as a novel material among various polymer materials. By varying the dopant concentration, the above properties can also be controlled [13, 14]. Strong polymeric films are fabricated by packaging industries using the film forming ability of PVA. This is possible due to some of the interesting properties of PVA such as easy processability, high mechanical strength and environmental stability [15]. PVA finds its use in different industries and it is a semicrystalline, non-toxic, and hydrophilic material which is also biocompatible and easily soluble in water [16].

Manufacturers use Polyvinyl Chloride (PVC or Vinyl) for the production of pipes, medical devices, wire and cable insulation due to its high strength thermoplastic material property. PVC has superior mechanical and physical properties for which it is the leading synthetic plastic polymer having third-largest production in the world. But, materials like polyethylene and polystyrene used as commodity plastics show better fluid plasticity and thermal stability than PVC [17]. For the improvisation of the above properties, research work has been carried out which excludes many handy experiments. These experiments are comprised of the addition of additives like plasticizers, heat stabilizers, lubricants, fillers and other polymers to PVC to uplift the desired properties [18]. The present study is focused on the formation of blends by identifying the interaction of polyvinyl alcohol and polyvinyl chloride with each other.

MATERIALS AND METHODS

Software Used

The analysis was carried out by using the *Materials studio* module of *Biovia software* (*Dassault Systemes of France*). Techniques like machine learning and standard algorithms are utilized by the software to predict the level of interaction.

Methodology

The structures of PVA and PVC were fed to the *synthia* menu of *Materials Studio*. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyvinylchloride as potential components of a composite was analyzed using Biovia Materials Studio. Wide range of polymer properties can be evaluated by BIOVIA Materials Studio Synthia using pre-defined correlations (advanced quantitative structure-property relationships). The properties of polymers along with small molecules were predicted by using *Group additive methods* for many years which are supposed to be extremely fast and easy to use. These methods are of great utility for rapid estimation of

any property of a material. This can be processed without a detailed understanding of the atomistic interactions which give rise to the specified property. But, there exist a major drawback of these methods which is nothing but the dependence of these methods on a database of group contributions. So, the property of a polymer cannot be calculated if it contains a group for which the group contribution cannot be estimated.

Synthia (Biovia) uses the topological information about the polymers in the predictive correlations and implementation of this method helps in overcoming the above limitation. Here, graph theory used to derive the connectivity indices is employed and there is no requirement of any database of group contributions. The properties of any polymer constituted by these nine elements such as; carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine and bromine can be predicted by the above method.

Heat capacity: Without changing the phase, the amount of heat needed to raise the temperature by 1°C of one unit weight of a substance is called heat capacity. Figure 1 shows that the heat capacity (Cp) of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite linearly increases with increasing value of mass fraction of vinyl alcohol.

Dielectric constant: The dielectric constant of a material may be defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure-3 shows that the dielectric constant of the composite linearly increases with increasing value of mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyvinylchloride to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. As per the result, the values of thermal conductivity and dielectric constant increases with increasing value of mass fraction of vinyl alcohol except heat capacity. Heat capacity for the blend shows a decreasing trend with increasing value of mass fraction of the base taken. Usually, components for a blend are identified experimentally. This in-silico study will help in determining the components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Polymeric blend having two or more components is the easiest and low cost way to generate hybrid polymer with improved properties. Strong molecular interaction in homogeneous blend is the key to enhance the physical and chemical properties of polymers. In this manuscript, we have tried to explore the compatibility of poly (biphenyl dimethylcarbonate) and poly(ethersulfone) to form a miscible blend using Biovia Materials Studio. The blending compatibility of these two polymers was studied based on free energy of mixing, phase diagram, chi parameter, and mixing energy. The obtained results depicted the immiscibility of these two polymers in the temperature range of 50 K to 500 K. However, higher temperature may lead the miscibility condition, as revealed from phase diagram. The coordination number was found to be 5. The highest number of configurations with respect to energy level was found to be -2.1 kcal/mol. This study may help in determining the optimal composition of pairs and temperature for the preparation of homogeneous blend without performing laboratory experiments and therefore, saving materials, money and time.

Keywords: Blend, in silico, biphenyl dimethylcarbonate, ether sulfone

INTRODUCTION

The current age is essentially managing the improvement of existing one in all areas of science and technology. Polymers are structurally designated with large molecular weight entities, having propagation of repeating units. It shows a reiteration in their separated auxiliary units and notable for their capacity to be used in day by day needs [1]. The much of the time utilized technique for altering the properties of polymers is their mixing with other polymers and it prompts the improvement in different properties like thermal [2], mechanical [3] and electrical properties [4]. The arrangement of miscible mixes permits most obviously changing the properties of polymers; nonetheless, there are not all that numerous sets of polymers shaping such mix [5]. In many cases, polymers are miscible just on account of a low proportion of one of them, or they are low- molecular weight or because of a proper

choice of the compatibilizer [6]. From the thermodynamic perspective, miscibility of a blend relies on the decline of Gibbs free energy of blending and identified with change in entropy and enthalpy. Subsequently, the examination of blending compatibility of two or more polymeric components is the essential parameter to plan hybrid polymers with improved properties. Besides, with the ongoing situation, hybrid polymers are broadly utilized with nanostructural filler (carbon nanotube, nanoclay, graphene, and so forth.) to convey magnificent properties, for example, electrical or semiconducting [7], thermal [8] and mechanical properties [9]. Among different polymers, polybiphenyldimethylcarbonate (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical capacity [10]. Because of these phenomenal properties, PC has been to a great extent utilized in electronic and electronic machines alongside car industry, having a yearly creation of 6 million tons. Ongoing report by Behboudi et. al.

[11] shows that PC is mixed with polyvinyl chloride (PVC) to set up the ultrafiltration film for water filtration. Then again, PC is additionally mixed with poly(vinylidene fluoride) (PVDF) to get ready precisely solid multicomponent nanocomposites with nanostructural enrichment of graphenenanoplates, carbon nanotube, and naturally adjusted montmorillonite [12]. In another report Wen et al. incorporated the graphene plates into mixture of polybutyleneterethalate and polycarbonate [13] to acquire electrical and thermal conductive materials. As per the literature review, a advanced sensing material was framed from the blend of PC with polystyrene to detect organic vapors with inclusion of multiwalled carbon nanotubes (MWCNTs) [14]. Polycarbonate mixed polysulfone material was reported with improved thermal and mechanical properties.[15].Therefore, examination of blending capability of polycarbonate with other polymer is the pressing need of ebb and flow research to create progressed useful materials. All the previously mentioned models depended on lab tests. For the most part, readiness of homogeneous mix in wet-lab condition requires colossal time and wastage of materials which can be limited by in-silico approach through material studio [16] of "Biovia"software. In present context, we are focusing to optimize the homogeneous blend composition of polybiphrnyldimethylcarbonate (PC) with poly(ether sulfone) (PES). Among various engineering polymers, polyether sulfone (PES) is a high-temperature sustaining thermoplastic polymer with striking strength and chemical stability from various organic solvents. It belongs to the polysulfone family and contains an aryl-SO_2 subunit in their long chain structures. Nonetheless, the intrinsic hydrophobic property of PES formulatesthis prepared material sensitive to membrane fouling, restricting its more wide-rangingrelevance in water treatment based on membrane. Due to high chemical stability it is also preferably used for gas separation in harsh environment. To improve the gas separation efficiency of PES, a few investigations have been performed. In a report, Adib et al. [17] incorporated the nanostructural silica to improve the gas separation.

However, blending of PES with other hydrophilic polymer is one of the easiest routes to improve the efficiency of the gas separation. In another report, Mannan et al. [18] explored the gas-permeation behavior of glassy poly(vinyl acetate) (PVAc)–PES hybrid films and PSF–PES film. Interestingly, it is found that the gas permeation properties of hybrid PSF–PES film is remain unaltered as compared to the properties of polyether sulfone. However on account of the PES–PVAc hybrid polymer, low selectivity was observed for gas separation and may be accounted as the phase separation in their blend. Kamal et al. [19] revealed that the blend with elastomers (like polydimethylsiloxane) leads to the improved gas penetration properties of the polydimethylsiloxane–PES hybrid. Akbarian et al.[20] prepared the PES based blend membranes for CO_2 gas separation with inclusion polyethylene glycol (PEG) as second polymer [20]. Therefore, the present in-silico approach of blend analysis between polybiphenyl dimethyl carbonate (PC) and polyether sulfone(PES) may be utilized to optimize the composition to fabricate desirable functional materials with some improved physical and chemical properties.

MATERIALS AND METHODS

Software Used: In this study different tools of Bioviasoftware (Materials studio) (Dassault Systemes of France) was used for this blend analysis. The software used the machine learning techniques and standard algorithms to calculate the mode of interaction.

Procedure: Poly (biphenyl dimethylcarbonate) and poly (ether sulfone) were prepared using the build menu of the Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polybiphenyl dimethyl carbonate was used as the base and poly (ether sulfone) was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed in order to gain knowledge regarding the compatibility of the components to form a blend.

RESULTS AND DISCUSSION

In this investigation, we have used polybiphenyldimethylcarbonate (PC) and poly(ether sulfone) as potential components of a blend and it was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

Where, ΔG_m — *Gibb's free energy of mixing*

ΔH_m = *Enthalpy of mixing*

ΔS_m = *Entropy of mixing*

T = *Absolute temperature*

The value of $T\Delta S_m$ is always positive in case of a blend, when entropy of mixing increases . As a result, the positive and negative sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. A miscible blend can be formed by the components when the free energy entropic contribution exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1, shows that the free energy involved in mixing is positive for all values of temperature, indicating the phase separation in the entire range of temperature. However, higher temperature may satisfy the condition of forming a single phase for these two polymeric components.

Phase Diagram: Fig. 2 represents the phase diagram of the blend having poly (biphenyl dimethyl carbonate) (PC) and polydimethylsiloxane (PES) in their composition. Phase diagram is particularly helpful in predicting the different region of varying miscibility in connection to the temperature and composition. In present figure 1200 K shows the upper critical solution temperature (UCST) above which single phase miscible region is observed. Fragmented metastable region is observed in between bimodal (blue lines) and spinodal lines (green lines). The region of phase separation is underlined by spinodal, whereas, binodalseperates the single-phase and meta-stable region. Again the system enters from single-phase state to the metastable state, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation along with growth of the phase separated domains. On the other hand, spinodal decomposition mechanism happens when the system leaps from a single-phase into the spinodal state of immiscibility the phases separate spontaneously.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi). Figure 2 shows that the blend of PC and PES has basically depicted the positive values of χ (chi) within a

temperature range of 50 K to 500 K. It confers the de-mixing of these two polymeric components due to mismatching of their cohesive in the entire range of temperature, studied. Therefore, represents a state of phase separation. However, poly (biphenyl dimethyl carbonate) (PC) and poly (ether sulfone) (PES) are not mixed to form a homogeneous blend in wide range of temperature and the data is well supported from the free energy of mixing of the blend.

Coordination Number: The coordination number Z_{ij} is defined as the number of molecules of type *j* that can be crowded around a single molecule of type *i*. The coordination number was determined for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It is understood that molecules which are not aligned on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 5.

Energy Distribution for Blend: Fig.4 shows the variation of population of different energy levels associated with pair having different configuration and orientation. It shows that the distribution is broad in nature. Maximum molecular population is observed to be centered around -2.1 kcal/mol, and distribution around this value is asymmetric in nature. As expected majority of pair configuration lies on the low energy value to attain a stable state.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low may be suitable for mixing. Figure 5 shows that the mixing energy for the system was small (19.5 kcal/mol) for the temperature range 50K-270 K. Afterward, increase in temperature leads to the higher values of free energy which eventually leads to the conclusion of phase separation at higher temperature. But at low temperature (50K-270K), mixing may be possible due to small positive values of free energy.

CONCLUSION

The possibility of use of polybiphenyl dimethyl carbonate and poly (ether sulfone) and to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 5. The maximum number of configurations with respect to energy level was found to be -15 kcal/mol. usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

In this work the compatibility of polyvinyl alcohol and poly-1, 2-α-D-glucose was studied to form a miscible blend using Biovia Materials Studio blend analysis.The combination of two or more components is said to be a blend. The compatibility of the two components was demonstrated based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at high temperature. The phase diagram indicated that a single phase can be obtained above 460 K which was the critical temperature. The coordination number was found to be 6.85 +/- 0.04. The highest number of configurations with respect to energy level was found to be -2.0 kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend, in silico, polyvinyl alcohol, poly-1, 2-α-D-glucose, biovia material studio.

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture. Blends or composites are the physical combination of more than one component where components do retain their identity in the mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process which provides an easy pathway develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. A composite/blend exhibit significantly diversephysic –chemical characteristics from those of its constituent components. In a composite the constituents remain physically separable and different from each other. Generally, a composite is a matrix materialwhere strong and stiff reinforcement is dispersedwith a soft and weaker components interaction [1-3].As repoted the enhanced properties of composites are mostlyaffected by their

microstructure and contact between matrix and reinforcing materials in the inter-phase state [4, 5].Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [6] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [7] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [8]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [9].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [10]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [11] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.Usually blends are prepared by trial and error methodandthis technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [12]) has been used to identify compatible pairs.

With all this available s polymers, polyvinyl alcohol (PVA) is a potential candidate due to its physical properties like high dielectric strength, easy film formation, adhesiveness [13, 14]. The polymer properties can be tuned by incorporating various impurities particle. PVA has very unique film forming ability which leads the material to packaging industry to form strong polymeric films due to its high mechanical strength, environmental stability and easy fabrication [15]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [16].

Researchers have found many applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the field of biology like toxic removal from body, drug delivery, insulin delivery[17]. It has been found that biopolymer blends possess good thermal stability [18].By adding glycopolymers (cellulose nanoscale fillers) in different polymers (polyvinyl alcohol or polylactic acid) we can synthesize nanocompositeshaving mechanical reinforcement and alternation of other properties [19].This study is intended to identify the interaction of polyvinyl alcohol andpoly-1, 2-α-D-glucose to form blends.

MATERIALS AND METHODS

Software Used: Biovia software with various tools and techniques (Dassault Systemes of France) was used for analysis. The standard algorithms along with machine learning techniques were used to predict the level of interaction.

Methodology: Polyvinyl alcohol and poly-1, 2-α-D-glucose were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and poly-1, 2-α-D-glucose was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1, 2-α-D-glucose as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

Where $\Delta G_m = Gibb's free energy of mixing$

$\Delta H_m = Enthalpy of mixing$

$\Delta S_m = Entropy of mixing$

$T = Absolute temperature$

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing are negative at around 160 Kandbeyong 500 K and positive for other temperature regeions studied here. The free energy decreases with increase in temperature (upto160 K) as evident from Eq. 1 and free energy increases with increase in temperature after 165 K upto 330 K.Furthet increase in the temrature it decreases gradually. The results indicated that the blend will lead to a homogeneous mixture for the temperature around 161 K and beyond 500 K. The trend shows a very good compatibility between polyvinyl alcohol and poly poly-1, 2-α-D-glucose with negative value of mixing energy for the above mentioned temperatures, which may form a perfect blend with significantly less effort.

Chi Parameter: The Flory–Huggins χ parameter explains the excess free energy of mixing and helps to identify the phase behavior for blending of polymers and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demising for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high or low for the low and high temperature range (500 K) respectively indicating mixing of the components at high temperature. The χ value decreased with increase in temperature. Thus at high temperature a miscible blend may be formed. This agrees with the free energy of mixing for the blend.

Coordination Number (CN): The coordination number Z_{ij} is the number of molecules of type *j* that can be surrounded by a single molecule of type *i*. The CN was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used for lattice calculation. It is predicted that molecules are not followed on a regular lattice mode as expected in the original Flory-Huggins theory. The coordination number is useful only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pair's method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 6.85 +/- 0.04.

Phase Diagram: The compatibility of binary mixtures can be obtained by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase region which is shown miscible lies above the critical temperature of around 460 K. This value indicated the fact that a single phase blend can be formed at a high temperature (higher than 460K).

b. Fragmented metastable regions existed between binodals and spinodals, and

c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.

When the system enters from one of the single phase region to the other metastable region, resembling crystallization of phase separation play an important role which is the slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.0kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 6 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature decreased the mixing energy upto 160 K. It indicates that mixing energy slowly increases with increase in temperature after 160 K upto 330 K and further increase in temperature with minimization of mixing energy. So, it is very much possible to mix the two components at high temperature with least mixing energy value. The homogeneous blend formation with polyvinyl alcohol as base might help formation of blend with high mechanical strength. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1, 2-α-D-glucose to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility above 460 K. The coordination number was found to be 6.85 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -2.0 kcal/mol. usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Polymerblends/composites are developed by varying the mass fraction of components to get anticipated properties. The desired property of a blend is its homogeneity, perhaps it may be heterogeneous. In this work, the in silicothermal and dielectric properties are explored taking polyvinyl alcohol and poly-1,2-α-D-glucose as components using Biovia material studio synthia analysis. The thermal and dielectric properties are exploredconcerning heat capacity, thermal conductivity, and dielectric constant. The results indicated that all those parameters decreased with anincrease in the mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money, and time.

Keywords: Synthia, in silico, polyvinyl alcohol, poly-1, 2-α-D-glucose, biovia material studio, thermal property, dielectric property

INTRODUCTION

Blends or composites are the physical combinations of more than one component where components do retain their identity in the mixture.The blend may be a homogenous or heterogeneous mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process that provides an easy pathwayto develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. A composite/blend's characteristics differs from it's constituent components which are physically distinct from each other. Usually, a composite is a matrix in which strong and stiff reinforcement is distributed but made of soft and weaker components [1-3].The upgraded properties of composites are predominantly governed by

their microstructure and interaction between matrix and reinforcing materials in the inter-phase region [4, 5].Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [6] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [7] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [8]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [9].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [10]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [11] were developed for the construction of bridges, light rail transit, mining, and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments. Usually, blends are prepared by trial and error method and this technique is a low cost and less time-consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [12]) has been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a suitable material as it has high dielectric strength, easy film formation, adhesiveness, and whose properties can be controlled by dopant concentrations [13, 14]. The film-forming ability of PVA is widely used in the packaging industry to form strong polymeric films due to their high mechanical strength, environmental stability, and easy processability [15]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible, and easily soluble in water [16]. Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition, and glucose-responsive insulin delivery [17]. It has been found that biopolymer blends possess good thermal stability [18].By adding glycopolymers (cellulose nanoscale fillers) in different polymers (polyvinyl alcohol or polylactic acid) we can generate nanocomposites resulting in mechanical reinforcement and alternation of other properties [19].This study is intended to identify the interaction of polyvinyl alcohol and poly-12-a-D-glucose to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly-1, 2-α-D-glucose were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work, the use of polyvinyl alcohol and poly-1, 2-α-D-glucoseaspotential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties.

Heat capacity: It is the amount of heatrequired to raise the temperature of one unit weight of a substance by 1°C without change of phase.Figure 1 shows that the heat capacity (Cp) of the composite decreases with increase in the mass fraction of vinyl alcohol.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient.It refers to the intrinsic ability of a material to transfer heat.Figure 2 shows that the thermal conductivity of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Dielectric constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant.Figure 3 shows that the dielectric constant of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1, 2-α-D-glucose to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant.The results indicated that allthree parametersdecreased with an increase in the mass fraction of vinyl alcohol. Usually, components for a blend are identified experimentally. This in silico study will help determine the properties of a composite without performing laboratory experiments saving materials, money, and time.

ABSTRACT

A blend is a combination of at least two components which gives superior properties than individual component. The heat capacity, thermal conductivity and dielectric constant of as-formed blend were studied using Biovia Material studio. The outcomes demonstrated that each one of those parameters decreased with increase in mass fraction of polyvinyl alcohol. That means heat capacity, thermal conductivity and dielectric constant of as-formed blend increased with increase in mass fraction of 1, 2-α-D-galactose. This study will help to determine pairs without doing experiments in laboratory sparing materials and time with low cost.

Keywords: In silico analysis; Dielectric properties; Thermal properties; Polyvinyl alcohol

INTRODUCTION

Blends or composites are materials containing more than one component. The components don't lose their character in the blend. They join and add to the property of the mix in this manner enhancing the quality of the material. Advancement of a solitary material with the ideal property includes significant research and time. A blend utilizes the advantages of different materials; mix them to get the wanted property. Thus a blend saves time to develop a new material thereby reducing the cost of improvement of products with required properties. Polymer blends can be made of at least two polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Among the different polymers, polyvinyl alcohol (PVA) is a auspicious material because of its high dielectric properties, easy film formation, adhesiveness and these properties can be influenced by dopant concentrations [8, 9]. The film forming ability of PVA is generally utilized in bundling industry to form strong polymeric films. It is a direct result of their high mechanical strength, environmental stability and easy processability [10]. Then again, PVA is hydrophilic, non-toxic, semi crystalline, easily soluble in water and biocompatible [11]. D-galactose has been used in combination with other materials in various applications in earlier literature [12]. Poly-1, 2-α-D-galactose has been demonstrated to be used in Curtius reaction. In this paper, the thermal and dielectric properties of blend of polyvinyl alcohol and poly-1, 2-α-D-galactose were analyzed at different mass fraction of vinyl alcohol using Discovery material studio which is new according to my knowledge.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly-1, 2-α-D-galactose were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1, 2-α-D-galactose as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties.

Heat capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite decreases linearly with increase in mass fraction of vinyl alcohol. Therefore we can say that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of 1, 2-α-D-galactose.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite decreases linearly with increase in mass fraction of vinyl alcohol. Therefore we can say that the thermal conductivity of the composite increases linearly with increase in mass fraction of 1, 2-α-D-galactose.

Dielectric constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite decreases with increase in mass

fraction of vinyl alcohol. Therefore we can say that the thermal conductivity of the composite increases linearly with increase in mass fraction of 1, 2-α-D-galactose.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1, 2-α-D-galactose to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The outcomes demonstrated that each one of those parameters decreased with increase in mass fraction of polyvinyl alcohol. That means heat capacity, thermal conductivity and dielectric constant of as-formed blend increased with increase in mass fraction of 1, 2-α-D-galactose. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without examining laboratory experiments that mean there is no use of any chemicals to analyze the above properties.

ABSTRACT

A blend is formed from the combination of two or more components. The compatibility of polyvinyl alcohol and poly-1, 2-α-D-galactose was studied to form a miscible blend using Biovia Materials Studio. The compatibility of the two components was demonstrated based on free energy of mixing, mixing energy and chi parameter. From the results, it was observed that the pair can have very good compatibility at low to high temperature without any phase separation. The coordination number was found to be 6.97 +/- 0.04. The highest number of configurations with respect to energy level was found to be -1.95 kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend; Biovia Material Studio; Compatibility; Polyvinyl alcohol; In silico analysis

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is incredibly tough to seek out multiple properties during a single material, it's suggested to mix totally different component thereby enhancing the properties of the material. Development of one material with the required property involves important analysis and time. A blend utilizes the benefits of various materials; mix them to urge the required property. Therefore a blend saves time to develop a brand new material thereby reducing the price of development of products with desired properties. Polymer blends may be made of two or additional polymers, or fibers and polymer, or particles and polymer.

Nano material incorporated polymers paved the way to multi-functional materials. Polymers assisted with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been taken to enhance mechanical properties and water resistance. Further, the improved fire retardant/fire proof materials have been reported [3]. There are reports of inorganic additives in polypropylene; that

can enhance flame retardancy without increasing the weight [4]. Researchers have given attention on synthesis and production of lightweight composite materials having high strength necessary for improving fuel efficiency in the field of transportation [5]. There are various applications of composites in structural Engineering because of high strength to weight ratio and resistance to corrosion. Thus, glass fiber incorporated polymers; latex polymer cementations composites [6] were synthesized for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have given attention on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Considering different polymers, polyvinyl alcohol (PVA) is a encouraging material because of its easy film formation, high dielectric strength, adhesiveness and its properties are often controlled by dopant concentrations [8, 9]. The film forming ability of PVA is wide employed in packaging trade to create sturdy compound films. It's as a result of their high mechanical strength, environmental stability and simple processability [10]. Further, PVA is non-toxic, hydrophilic, semi crystalline, biocompatible and easily soluble in water [11]. Scientist have found different applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12]. It has been found that biopolymer blends possess good thermal stability [13].This study is intended to identify the interaction of polyvinyl alcohol and poly-1, 2-α-D-galactose to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyvinyl alcohol and poly-1, 2-α-D-galactose was prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and poly-1, 2-α-D-galactose was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1, 2-α-D-galactose as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = *Gibb's free energy of mixing*

ΔH_m = *Enthalpy of mixing*

ΔS_m = *Entropy of mixing*

T = *Absolute temperature*

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpy contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always negative or less than zero for the temperatures studied. The free energy decreases with increase in temperature (up to 275 K) as evident from Eq. 1 and then free energy increases with increase in temperature (up to 500 K). The results indicated that the blend will absolutely lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyvinyl alcohol and poly-1, 2-α-D-galactose with negative value of mixing energy, which may lead to form a perfect blend with significantly less effort.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).

Figure 2 shows that the χ value is very small or negative for the temperature range studied (50 to 500 K) indicating very good mixing. The χ value increased with an increase in temperature at various temperatures ranges (50 K to 500 K). There is a very good possibility of homogeneous mixing with such small value of χ which agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 6.97 +/- 0.04.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.95 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature results the increase in mixing energy. It also shows that mixing energy gradually increases with increase in temperature with varying the temperature from 50 K to 500 K. So, it is very much possible to mix the two components at any feasible temperature with least mixing energy value.

The formation of non homogeneous blend with polyvinyl alcohol as base might help formation of blend with high mechanical strength. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1, 2-α-D-galactose to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 6.97 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -1.95 kcal/mol. usually components for a blend are identified experimentally. This in silico study will help to determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Polymeric blend having two or more components is the easiest and low cost way to generate hybrid polymer with improved properties. Strong molecular interaction in homogeneous blend is the key to enhance the physical and chemical properties of polymers. In this manuscript, we have tried to explore the compatibility of poly (biphenyl dimethyl carbonate) and polydimethylsiloxaneto form a miscible blend using Biovia Materials Studio. The blending compatibility of these two polymers was studied based on free energy of mixing, phase diagram, chi parameter, and mixing energy.The obtained results depicted that the compatibility between these two polymers only possible in the temperature range of 270 K to 300 K. However, higher and lower temperature may lead the phase separation between these two polymers. But at very higher temperature (1080 K) single phase may exist as revealed from the phase diagram. The coordination number wasfound to be 3.14 +/- 0.02. The highest number of configurations with respect to energy level was found to be -2.5 kcal/mol. This study may help in determining the optimal composition of pairs and temperature for the preparation of homogeneous blend without performing laboratory experiments and therefore, saving materials, money and time.

Keywords: Blend; *In silico* analysis Poly (biphenyl dimethyl carbonate) and poly dimethyl siloxane

INTRODUCTION

The recent age is basically dealing with the improvement of existing one in all dimensions starting from the industrial to biomedical sectors. Polymers are simply long chain macromolecules with man-made or natural origins. It shows a repetition in their distinguished structural units and well known for their ability to be utilized in daily needs [1]. The frequently-used method of modifying the properties of polymers is their blending with other natural or synthetic polymers and it leads to the improvement in various properties like thermal [2], mechanical [3] and electrical properties [4]. The preparation of miscible blends allows most strongly changing the properties of

polymers; however, there are not so many pairs of polymers forming such blends [5]. In majority of cases, polymers form miscible blends only in the case of a low content of one of them , or they are low molecular weight or due to the addition of a compatibilizer [6]. From the thermodynamic point of view, miscibility of a blend depends upon the decrease of Gibbs free energy of mixing and related to change in entropy and enthalpy. Therefore, the investigation of mixing compatibility or miscibility of a pair of blends is the crucial parameter to prepare hybrid polymers with improved properties. Moreover, with the recent scenario, hybrid polymers are widely used with nanostructural filler (carbon nanotube, nanoclay, graphene, etc.) to deliver excellent properties such as electrical or semiconducting [7], thermal [8] and mechanical properties [9]. Among different polymers, poly (biphenyl dimethyl carbonate) (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical strength [10]. As a resultof these excellent properties, PC has been largely employed in electronic and electronic appliances along with automotive industry, having an annual production of 6 million tons. Recent report by Behboudiet. al. [11] shows thatPC is blended withpolyvinyl chloride (PVC)to preparethe ultrafiltration membrane for water purification. On the other hand, PC is also blended with poly (vinylidene fluoride) (PVDF) to prepare mechanically strong multicomponent nanocomposites with nanostructural reinforcement of graphenenanoplates, carbon nanotube, and organically modified montmorillonite [12].

In another recent report Wen et al. reinforced the graphene plates into blend of polybutyleneterethalateand polycarbonate [13] to obtain electrical and thermal conductive materials. The unique material, formed from the blend of PC with polystyrene is also reported to sense organic vapours with incorporation of multiwalled carbon nanotubes (MWCNTs) [14]. Polycarbonate blendedpolysulfone material is recently observed to have improved thermal and mechanical properties.[15]Therefore,investigationof blending compatibility of polycarbonate with other polymer is the urgent need of current research to develop advanced functional materials.All the above mentioned examples relied on laboratory experiments. Usually, preparation of homogeneous blend in wet-lab condition requires huge time and wastage of materials which can be minimized by in-silico approach through material studio [16] of "Biovia" software. In present context, we are focusing to optimize the homogeneous blend composition of polybiphrnyldimethylcarbonate (PC) with polydimethylsiloxane (PDMS). It is a polymeric organosilicon compound, particularly known for its unusual rheological behaviors. Moreover it is optically clear, non-toxic and non-flammable. Polydimethylsiloxane (PDMS) shows wide applications like contact lenses, medical devices and preparing elastomer materials. It is also used in making of lubricants and heat-resistant tiles. Recently, Adreeset. al. [17] prepared the PDMS based blend membranes with polyvinyl chloride-co-vinyl acetate (PVCA) for CO_2seperation. Polydimethylsiloxane is also used in biomedical application like maxillofacial prosthetics, artificial blood vessels and articular cartilage replacement, when it is blended with poly ether (ether) ketone (PEEK) [18]. Therefore, the present in-silico approach of blend analysis between polybiphenyldimethyl carbonate (PC) and polydimethylsiloxane (PDMS) may be utilized to optimize the composition to fabricate desirable functional materials with some improved physical and chemical properties.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for this blend analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Poly (biphenyl dimethyl carbonate) and polydimethylsiloxane were prepared using the build menu of theMaterials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. polybiphenyl dimethyl carbonate was used as the base and polydimethyl siloxanewas used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed in order to gain knowledge regarding the compatibility of the components to form a blend.

RESULTS AND DISCUSSION

In this investigation, we have used poly (biphenyl dimethylcarbonate) (PC) and polydimethylsiloxaneas potential components of a blend and it was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$\Delta G_m - \Delta H_m - T\Delta S_m$ (1)

Where, $\Delta G_m = Gibb\ s\ free\ energy\ of\ mixing$

$\Delta H_m = Enthalpy\ of\ mixing$

$\Delta S_m = Entropy\ of\ mixing$

$T = Absolute\ temperature$

The value of $T\Delta S_m$ is always positive in case of a blend, since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1, shows that the free energy involved in mixing is initially positive and goes on decreasing with increase of temperature upto275 K, after that starts increasing and approaches to a positive value (~2.7 Kcal/mole) at a temperature of 500 K. The initial decrement in the free energy with increase in temperature upto 275 K from positive value to slight negative value is observed. Small negative values at 275 Kindicates that the blend with all compositions of PC and PDS have a homogeneous composition at temperature 275K. This offers a very good compatibility between these two polymers, i.e. polybiphenyl dimethyl carbonate (PC) and polydimethylsiloxane and therefore, showing the best way to prepare the hybrid polymer film. But as we increase the temperature above (~300K), homogeneity in the polymer blend is disturbed and a immiscible pair is obtained instead of a perfect blend.

Phase diagram: Fig. 2 represents the phase diagram of the blend having poly (biphenyl dimethyl carbonate) (PC) and polydimethylsiloxane (PDMS) in their composition. Phase diagram is particularly helpful in predicting the different region of varying miscibility in connection to the temperature and composition. In present figure 1080 K shows the upper critical solution temperature (UCST) above which single phase miscible region is observed. Fragmented metastable region is observed in between bimodal (blue lines) and spinodal lines (green lines). The region of phase separation is underlined by spinodal, whereas, bimodal separates the single-phase and meta-stable region.When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).Figure 2 shows that the blend of PC and PDMS has basically depicted the positive values of χ (chi) within a temperature range of 50 K to 500 K. It confers the de-mixing of these two polymeric components due to mis-matching of their cohesive energy within the whole temperature range. But, interestingly, near the temperature of

270-300 K, it approaches to value with showing the possibility of mixing. Above this temperature (> 300 K), χ of this blending again approaches to a high positive value andtherefore, represents a state of phase separation. However, poly (biphenyldimethylcarbonate) (PC) and polydimethylsiloxane (PDMS) are well mixed to form a homogeneous blend only in the temperature range of 270-300 K and the data is well supported from the free energy of mixing of the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 3.10 +/- 0.02.

Energy Distribution for Blend: Fig.4 shows the variation of population of different energy levels associated with pair having different configuration and orientation. It shows that the distribution shows a broad curve with long tail. Maximum population is centered around -2.5 Kcal/mol energy and distribution around this value is asymmetric in nature. As expected majority of pair configuration lies on the low energy value to attain a stable state of miscibility.

Mixing Energy: A small value of mixing is generally allows the polymeric components to mix well to get the homogenous blend. Thus, the temperature at which the mixing energy is low may be suitable for mixing. Figure 5 shows that the mixing energy for the system was small for the temperature range of 270-300K, while it shows the higher values for other temperature domain. Hence, the mixing of these two polymeric component is only possible in the region of 270-300K.

CONCLUSION

The possibility of use of poly (biphenyl dimethyl carbonate) and polydimethyl siloxane and to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have the compatibility at 270-300K; beyond that phase separation may results. The coordination number was found to be 3.14 +/- 0.02. The maximum number of configurations with respect to energy level was found to be -2.5 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is always a composition of two or more components and it is desirable to have homogeneityin a blend. In this paper, we have tried to explore the compatibility of polyacrylic acid andpoly-1,3-α-D-Galactoseto form a miscible blend using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, and mixing energy. The results indicated that the pair havea very good compatibility with a positive value of mixing energy within temperature range considered. The coordination number was found to be 7.22 +/- 0.05. The highest number of configurations with respect to energy level was found to be -2.2 kcal/mol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: In silico analysis, Blend, Biovia Materials Studio, polyacrylic acid, poly-1,3-α-D-Galactose.

INTRODUCTION

Blends or composites are materials containing more than one component. The components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance

flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12].It has been found that biopolymer blends possess good thermal stability [13].This study is intended to identify the interaction of polyacrylic acid and poly-1,3-α-D-Galactoseto form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyacrylic acid and poly-1,3-α-D-Galactosewere prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and poly-1,3-α-D-Galactosewas used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and poly-1,3-α-D-Galactoseaspotential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where $\Delta G_m = Gibbs\,free\,energy\,of\,mixing$

$\Delta H_m = Enthalpy\,of\,mixing$

$\Delta S_m = Entropy\,of\,mixing$

$T = Absolute\,temperature$

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive for the temperatures studied. The free energy decreases with increase in temperature for the system under study as is evident from Eq 1. The results

indicated that the blend will not supportthe formation of a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows the mismatching between polyacrylic acid and poly-1,3-α-D-Galactosewithpositive value of mixing energy and thus getting a perfect blend within the temperature range is somewhat intricate.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi).

Figure 2 shows that the χ value is positive within the temperature range under study (50K to 500K) indicating very poor mixing. The χ value decreasedwith increase in temperature constantly.Thus there is a possibility of getting homogeneous mixturebetween the polymers taken at a very high temperature.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this study the coordination number was found to be7.22 +/- 0.05.

Energy Distribution for Blend: The generation of different orientations using the pairsmethod may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreasedsignificantly. The maximum frequency was observed for the energy level of around -2.2kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing.The mixing energy for the system is positive within the temperature range studied as shown in the Figure 5. The graph indicated that an increase in temperatureincreased the mixing energy consistently and exponentially from 25kcal/mol to 35kcal/mol for a temperature increment of 50K to 500K.So,the mixing of the two components under study needs very high energy within the temperature range under study.

CONCLUSION

The possibility of use of polyacrylic acid and poly-1,3-α-D-Galactoseto form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the components within the pair are notcompatiblewithin the temperature range 50K to 500K. The coordination number was found to be 7.22 +/- 0.05. The maximum number of configurations with respect to energy level was found to be -2.2 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Polyacrylic, Polyacrylochloride composite

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were

developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. A broad variety of applications of acrylic polymers in dental surgery as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, super absorbent polymer, ion-exchange resin, etc.[10].

Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH.It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have used polyacrylochloride in combination with other materials to act as adsorbent [12]. Polyacrylochloride have been reported to be used in Curtius reaction. This study is intended to identify the interaction of polyacrylic acid and polyacrylochloride to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systems of France) was utilized for analysis. The software applies machine learning schemes and standard algorithms to forecast the standard of interactivity.

Methodology: The structures of polyacrylic acid and polyacrylochloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acid on the mechanical properties of the composite

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and polyacrylochloride as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia utilizes pre-arranged correlations (advanced quantitative structure-property relationships) to assess a broad range of polymer applications. Group additive methods were utilized for several years to forecast the applications of polymers as well as tiny molecules. These processes are very rapid and easy to utilize. In Consequence, they are of biggest usefulness when a very fast guessing of a property is needed without a thorough knowledge of the atomistic interactions that give rise to it. However, the main limitations of this process are their dependence on a database of group contributions. So, if a polymer carries a group for which the group contribution cannot be evaluated, then the property of that polymer cannot be estimated. To overcome this shortcoming, the process executed in Synthia utilizes topological knowledge about polymers in the anticipating correlations. The correlations indices obtained from graph theory are applied. Thus, no database of group contributions is needed and properties may be forecasted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat capacity: It is the amount of warmth needed to rise the temperature of one unit weight of a substance by 1°C without variation of phase. Figure 1 shows that the heat capacity (Cp) of the composite rises linearly with rise in mass fraction of acrylic acid.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite rises linearly with rise in mass fraction of acrylic acid.

Dielectric constant: It is determined as the fraction of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with rise in mass fraction of acrylic acid.

CONCLUSION

The possibility of use of polyacrylic acid and polyacrylochloride to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a combination of more than one component or constituents. The desired property of a blend is its homogeneity. The composition of polyacrylic acid and polyurea to provide desired mechanical properties of the blend was explored using Biovia Material Studio. The composition of the blend was analyzed concerning permeability properties.The molar volume increased and density decreased with an increase in acrylic acid fraction. The permeability properties of the composite were studied based on the permeability of oxygen, nitrogen, and carbon dioxide. The results indicated that the permeability for all the gases has exponential growth from 0.8 to 1-mole fraction of acrylic acid. This study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

Keywords: polyacrylic acid, polyurea, in silico, permeability

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.Nanomaterial modified polymers paved the way for multifunctional materials. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time, and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects, etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not irritate [11]. This study is intended to identify the interaction of polyacrylic acid and polyurea to form blends.Polyurea is a type of elastomer that is derived from the reaction product of an isocyanate component and a synthetic resin blend component through step-growth polymerization. The isocyanate can be aromatic or aliphatic in nature. It can be monomer, polymer, or any variant reaction of isocyanates, quasi-prepolymer or a prepolymer. The prepolymer or quasi-prepolymer can be made of an amine-terminated polymer resin, or a hydroxyl-terminated polymer resin [12].

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyacrylochloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of the weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and poly urea as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite increases with an increase in mass fraction of acrylic acid.

Density: Increase in density indicates a decrease in porosity. A higher porosity will enhance the surface area making it suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases with an increase in mass fraction of acrylic acid.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates a longer time lag for the gas to pass through the membrane. Figure 3 show that the permeability of oxygenthrough the composite has exponential growth from 0.8 to 1-mole fraction of acrylic acid.

Figure 4 show that the permeability of nitrogenthrough the composite has exponential growth during 0.8 to 1-mole fraction of acrylic acid. Figure 5 show that the permeability of carbon dioxide through the composite has exponential growth from 0.8 to 1-mole fraction of acrylic acid.

CONCLUSION

The possibility of the use of polyacrylic acid and polyureato form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed concerningpermeability properties.The molar volume increased and density decreased with an increase in acrylic acid fraction. The permeability properties of the composite were studied based on the permeability of oxygen, nitrogen, and carbon dioxide. The results indicated that the permeabilityfor all the gases has exponential growth from 0.8 to 1-mole fraction of acrylic acid.Usually components for blends are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

Keywords: polyvinyl alcohol, polyethersulfone, in silico, permeability

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture. Blends or composites are the physical combinations of more than one component where components do retain their identity in the mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process that provides an easy pathway to develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [2]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without

increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.

Usually, blends are prepared by trial and error method and this technique is a low cost and less time-consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness, and whose properties can be controlled by dopant concentrations [8, 9]. The film-forming ability of PVA is widely used in the packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability, and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible, and easily soluble in water [11].

Polyethersulfone (PES) is one of the most important engineering polymeric materials. This polymer is extensively used in membrane separation devices, such as microfiltration and ultra filtration (UF) process in the fields of food, plasma separator, biomedicine, hemodialysis, and water purification, etc.[12-15]. Besides, it displays exceptional thermal, oxidative, and hydrolytic stability as well as good mechanical and film-forming properties. It has been reported that blending PES with other polymers has addressed the surface physical and chemical properties concerning improved membrane properties, modifications of the pore structure, etc. [16]. This study is intended to identify the interaction of polyvinyl alcohol and poly(ether sulfone) to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyacrylochloridechloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of the weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcoholand polyethersulfone as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. ABSTRACT

A blend is a combination of more than one component or constituents. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol acid and polyethersulfone to provide desired mechanical properties of the blend was explored using Biovia Material Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio, and brittle stress fracture. The results indicated that the value of brittle stress fracture has no change and other properties increased with an increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money, and time.

Keywords: mechanical, in silico,polyvinyl alcohol, polyethersulfone

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture. Blends or composites are the physical combinations of more than one component where components do retain their identity in the mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process that provides an easy pathway to develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [2]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.

Usually, blends are prepared by trial and error method and this technique is a low cost and less time-consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness, and whose properties can be controlled by dopant concentrations [8, 9]. The film-forming ability of PVA is widely used in the packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability, and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible, and easily soluble in water [11].

Polyethersulfone (PES) is one of the most important engineering polymeric materials. This polymer is extensively used in membrane separation devices, such as microfiltration and ultrafiltration (UF) process in the fields of food, plasma separator, biomedicine, hemodialysis, and water purification, etc.[12-15]. Besides, it displays exceptional thermal, oxidative, and hydrolytic stability as well as good mechanical and film-forming properties. It has been reported that blending PES with other polymers has addressed the surface physical and chemical properties concerning improved membrane properties, modifications of the pore structure, etc. [16]. This study is intended to identify the interaction of polyvinyl alcohol and poly(ether sulfone) to form blends.

However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composites increases with an increase in mass fraction of polyvinyl alcohol.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the compositesincreases with an increase in mass fraction of polyvinyl alcohol.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the compositesincreases with an increase in mass fraction of polyvinyl alcohol.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases with an increase in mass fraction of polyvinyl alcohol.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite has no change with increase in mass fraction of acrylic acid

CONCLUSION

The possibility of the use of polyvinyl alcoholand polyethersulfone to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed concerning mechanical properties. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio, and brittle stress fracture. The results indicated that the value of brittle stress fracture has no change and other properties increased with an increase in mass fraction of polyvinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyacrylic acid and polyurea to provide desired mechanical properties of the blend was explored using Biovia Material Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio, and brittle stress fracture. The results indicated that the values of all the properties decreased with an increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money, and time.

Keywords: mechanical, in silico,polyacrylic acid, polyurea

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. Nanomaterial modified polymers paved the way for multifunctional materials. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio

and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time, and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects, etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not irritate [11]. This study is intended to identify the interaction of polyacrylic acid and polyurea to form blends. Polyurea is a type of elastomer that is derived from the reaction product of an isocyanate component and a synthetic resin blend component through step-growth polymerization. The isocyanate can be aromatic or aliphatic in nature. It can be monomer, polymer, or any variant reaction of isocyanates, quasi-prepolymer or a prepolymer. The prepolymer or quasi-prepolymer can be made of an amine-terminated polymer resin, or a hydroxyl-terminated polymer resin [12].

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyacrylochloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of the weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acidand polyurea as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite decreases with an increase in mass fraction of acrylic acid

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite decreases with an increase in mass fraction of acrylic acid.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite decreases with increase in mass fraction of acrylic acid.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite decreases with an increase in mass fraction of acrylic acid.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite decreases with increase in mass fraction of acrylic acid

CONCLUSION

The possibility of the use of polyacrylic acid and polyureato form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed concerningmechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio, and brittle stress fracture. The results indicated that the values of all the properties decreased with an increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed concerning heat capacity, thermal conductivity, and dielectric constant. The results indicated that heat capacity and thermal conductivity decreased but dielectric constant increased with an increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money, and time.

Keywords: thermal, dielectric,polyvinyl alcohol, in silico, polyethersulfone

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture. Blends or composites are the physical combinations of more than one component where components do retain their identity in the mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. The development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process that provides an easy pathway to develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials [2]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in

structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments.

Usually, blends are prepared by trial and error method and this technique is a low cost and less time-consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness, and whose properties can be controlled by dopant concentrations [8, 9]. The film-forming ability of PVA is widely used in the packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability, and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible, and easily soluble in water [11].

Polyethersulfone (PES) is one of the most important engineering polymeric materials. This polymer is extensively used in membrane separation devices, such as microfiltration and ultrafiltration (UF) process in the fields of food, plasma separator, biomedicine, hemodialysis, and water purification, etc.[12-15]. Besides, it displays exceptional thermal, oxidative, and hydrolytic stability as well as good mechanical and film-forming properties. It has been reported that blending PES with other polymers has addressed the surface physical and chemical properties concerning improved membrane properties, modifications of the pore structure, etc. [16]. This study is intended to identify the interaction of polyvinyl alcohol and poly (ether sulfone) to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyacrylochloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of the weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyether sulfone as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite decreases with an increase in mass fraction of polyvinyl alcohol.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite decreases with an increase in mass fraction of polyvinyl alcohol.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with an increase in the mass fraction of polyvinyl alcohol.

CONCLUSION

The possibility of the use of polyacrylic acid and polyurea to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed concerning heat capacity, thermal conductivity, and dielectric constant. The results indicated that heat capacity and thermal conductivity decreased but dielectric constant increased with an increase in mass fraction of polyvinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time

waterside buildings. All the above-mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time, and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects, etc. [8], bone repair [9], dispersing agent, super absorbent polymer, ion-exchange resin, etc. [10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not irritate [11]. This study is intended to identify the interaction of polyacrylic acid and polyurea to form blends. Polyurea is a type of elastomer that is derived from the reaction product of an isocyanate component and a synthetic resin blend component through step-growth polymerization. The isocyanate can be aromatic or aliphatic in nature. It can be monomer, polymer, or any variant reaction of isocyanates, quasi-prepolymer or a prepolymer. The prepolymer or quasi-prepolymer can be made of an amine-terminated polymer resin, or a hydroxyl-terminated polymer resin [12].

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polyacrylochloride were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of the weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acidand polyurea as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite increases with an increase in mass fraction of acrylic acid.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite decreases with an increase in mass fraction of acrylic acid.

.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite decreases with an increase in mass fraction of acrylic acid.

CONCLUSION

The possibility of the use of polyacrylic acid and polyureato form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed concerning heat capacity, thermal conductivity, and dielectric constant. The results indicated that heat capacity increased but thermal conductivity and dielectric constant decreased with an increase in mass fraction of polyacrylic acid. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money, and time.

ABSTRACT

A blend is created by the combination of two or more components. The compatibility of polyvinyl alcohol andpoly ethylene Terephthalate were study to form a miscible blend using Biovia Materials Studio. The compatibility of the two components was demonstrated based on free energy of combination, chi parameter, and mixing energy. The results indicated that the pair can become compatible only high temperature. Phasegraph indicated that a single phase can be obtained above 7500K which was the critical temperature. The coordination number was found to be 8.43 **+/-** 0.05. The highest number of configurations with respect to energy level was found to be -1.93Kal/Mol kcal/mol. This study will not only help to determine pairs without performing laboratory experiment but also less time consuming and low cost process.

Keywords: Blend; Insilico; Polyvinyl alcohol; Polyethylene terephthalate.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to mix dissimilar components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of improvement of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material customized polymers paved the way to multi useful materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber

composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire evidence materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy lacking increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite material having high strength important for enhancing fuel efficiency in the field of transport [5]. There is application of composites in structural Engineering due to high strength to weight ratio and resistance to decay. Thus, glass fiber durable polymers, latex polymer cementations composites [6] were developed for building of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mention example relied on laboratory experiments.

Usually blends are prepared by test and fault method andthis method is a low cost and less time consuming method. Thus, researchers have focused on the use of in silicomove toward to develop new blends. Software (Materials Studio [7]) has been used to identify well-matched pairs. Among the a mixture of polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, simple film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is extensively used in covering industry to form strong polymeric films. It is because of their high mechanical power, environmental stability and easy processability [10]. On the other hand, PVA is poisonous, semicrystalline, hydrophilic, biocompatible and simply soluble in water [11].

The consumption of plastics in Western Europe is of 38 million tonnes per year, the majority of which are used in the production of plastic packaging, household and domestic products, electrical and electronic goods [12]. There is also significant consumption of plastics for the structure and construction industry and automotive industry. The two main types of plastics are thermoplastics, which soften when heated and harden again when cooled, and thermosets, which harden by curing and cannot be re-moulded. About 80 % of plastics used in Western Europe are thermoplastics [13].For many waste landfills is the largest route for disposal throughout the countries of Europe. For some countries, including Lithuania, more than 60 % of municipal solid waste is disposed of to landfill [14]. Plastics make up high proportion of waste that volume and range used increases dramatically. Although plastics make up between 5 wt.% and 15 wt.% of municipal solid waste it comprises 20 % – 30 % of the volume [13]. Most plastics are non-degradable and take a long time to decompose, possibly up to hundreds of years – although no-one knows for certain as plastics have not existed for long enough, when they are land filled. It is estimated that only about 50 % of the plastics produced in Western Europe each year are available for collection and recycling [12 – 14]. According to the experts from Kaunas University of Technology in Lithuania plastics reach about 82 thousands tones of municipal solid waste in 2004. It comprised about 24 kg for one inhabitant [15]. Waste recycling in Lithuania increases constantly and during 2000–2006 it ranges between 20 – 35 thousand tonnes per year [16]. According to the Environmental Protection Agency (EPA) "recycling" is considered to be processing of waste to make new article. There are divided three distinct approaches to the recycling of post-consumer plastic materials : 1) it could be reused directly; 2) undergo physical reprocessing, for example, grinding, melting and reforming; 3) be subjected to chemical treatment, when components are isolated and reprocessed for use in manufacture. A new widespread nomenclature of recycling was adopted by EPA. Primary recycling involves the use of pre-consumer industrial scrap and salvage, while physical reprocessing refers as secondary recycling and chemical processing as tertiary recycle [16].

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilize apparatus learning technique and standard algorithms to predict the level of communication.

Methodology: Polyvinyl alcohol andpoly ethylene Terephthalate to be prepared using the build menu of Materials Studio. The structures of the components were optimized using the mechanismto be used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and poly ethylene Terephthalate was used as

screen. After estimate the blends->analysis menu of Materials studio was use to create various data. The data were analyzed and the compatibility of the mechanism to form a blend was analyzed.

RESULTS AND DISCUSSION

The use of polyvinyl alcohol and poly ethylene Terephthalate as potential mechanism of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: The blend is said to be miscible if it is homogeneous. A negative value of free energy of combination indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggest that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = Gibb's free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = Entropy of mixing

T = Absolute temperature

The significance of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m at all times depends on the value of the enthalpy of mixing ΔH_m. The mechanism can mix to form a miscible blend only if the entropic contribution to free energy exceed the enthalpy contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is negative at around 140 Kandbeyong 500 K and positive for other temperature regeions studied here. The free energy decreases with increase in temperature (upto 140 K) as evident from Eq. 1 and free energy increases with increase in temperature after 145 K. then increase in the temperature it decreases gradually. The domino effect indicated that the mixture will take away to a identical mixture for the heat short 146K and beyond 500K. the trend shows a exceptionally agreeable compatibility between polyvinyl alcohol and polyethylene terephthalate with depressing significance of amalgamation energy for the above mentioned temperature.

Chi Parameter: The Flory-Huggins parameter describe the surplus free energy of combination and helps to explicate segment manner for polymer which are chemically similar, a momentous inequality in interrelated energy density leads to a extreme rate and, hence , a bigger pouring prize open for segment separation. So a exalted esteem of for chemically dissimilar polymers be a sign of meager mixing. For chemically comparable polymers having insignificant interrelated energy disaparity quantity is predictable to be small. However, nearby is a attempt of demixing for adequately lengthy chains. Architectural and numerical differences between the apparatus preclude them in a mixture from occupying the unaffected configuration accomplished in the nothing short of phase. Polymer area philosophy container predict that a difference in procession strength for chemically analogous machinery may pointer to a peak unquestionable importance of (chi).

Figure -2 shows that the set great store by is high point for the depths fever go and sad for the extreme hotness choice (500K) indicating amalgamation of the mechanism at high point temperature. The ⋅ merit decreased with raise in temperature. in this manner at important fever near is a leeway to variety a miscible blend. This agrees with the free energy of combination for the blend.

Coordination Number: The coordination number a_{ij} is the add up to of molecules of type 'j' that tin be packed around a lone molecule of type 'i'. the coordination number was calculate for each of the promising molecular pairs difficult in molecular simulations. The "Blends" module of materials studio differed from the Flory-Huggins from and second-hand an off-lattice calculation. It is understood that molecules are not agreed on a normal pattern as

probable in the creative Flory-Huggins theory. The coordination figure is large simply at what time the mechanism of the double mixture declares alike volumes or rise areas. It is intricate to rub on the pairs style in crucial a coordination add up to for a dual system in which the workings are not similar in size. In this look at carefully the coordination number was institute to be 8.43 +/- 0.05.

Energy Distribution for Blend: The group of unlike orientations via the pairs fashion may be the indication to configuration of unreliable energy levels. Figure 3 shows the plot of frequency (PE) against energy levels. It shows that the dissemination is rather irregular and at hand is a long, low-energy end. The quantity of configuration with energy higher than the peak respect decrease significantly.The maximum frequency was experiential for the energy level of around -1.93Kal/Mol .

Mixing Energy:A insignificant meaning of mixing energy preserve favors the mix process. Thus, the heat at which the incorporation energy is low container be elected for assimilation consider figure 4 shows the incorporation energy for the system was little for the high temperature studied. The diagram indicated that increase in temperature the addition energy up to 140K. it is and shows that combination energy steadily boost with add to fever after 140K up to 460K. So, it is same a large deal possible to the element at area of high pressure with superior amalgamation energy value

CONCLUSION

The scope of spending of polyvinyl alcohol and polyethylene terephthalate to custom a identical bring together was explored via Biovia material studio. The compatibility was analyzed based on free energy of mixing, inner self parameter and assimilation energy. The coordination come to was originate to be 8.43 +/- 0.05. the maximum number of configurations with think a lot of to energy smooth was bring into being -1.93Kal/Mol. As a rule apparatus for a mixture are identified experimentally this insillico study will did power mechanism of a mix together without performing arts laboratory experiment economy materials, funds and time.

ABSTRACT

This article intends to explore the compatibility of polyacrylic acid and poly(biphenyl dimethyl carbonate)to form a polymeric blend using Biovia Materials Studio.Polymeric blend is a physical combination of two or more polymers to develop hybrid polymer with enhanced properties. A blend may lead to Strong/weak molecular interaction to provide new properties which is desirable for various applications. The compatibility of the two components was studied based on the free energy of mixing, chi parameter, phase diagram, and mixing energy. The results indicated that the pair can become compatible only at high temperatures. Phase diagram indicated that a single phase can be obtained above 1350 K which was the critical temperature. The coordination number was found to be 7.84 +/- 0.05 The highest number of configurations for energy level was found to be -2.0 kcal/mol. The phase separation might lead to its use as porous material to be used as adsorbent. This study may help in determining the optimum composition/parameters required to prepare a homogeneous blend without performing laboratory experiments and therefore, saving materials, money, and time.

Keywords: Blend analysis, in silico, polyacrylic acid, poly-1, 2-α-D-glucose, biovia material studio, poly(biphenyl dimethyl carbonate)

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture of more than one components with modified physical and chemical properties than the individual components. Blends or composites are the physical combination of more than one component where components do retain their identity in the mixture. A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending

is a process which provides an easy pathway develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. A composite/ blend possess significantly different chemical and physical characteristics from those of its constituent components. In a composite the constituents remain physically separable and distinct from each other. Usually, a composite is a matrix in which strong and stiff reinforcement is distributed but made of a soft and weaker components [1-3]. The upgraded properties of composites are predominantly governed by their microstructure and interaction between matrix and reinforcing materials in the inter-phase region [4, 5]. Nano material modified polymers paved the way to multi functional materials.[6] Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [7] have drawn attention. Biodegradable polymers- natural fiber composites [8] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [9]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [10]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [11]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [12] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [13]) have been used to identify compatible pairs. Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [14], bone repair [15], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[16].Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation [17].

Poly(biphenyl dimethyl carbonate) has an amorphous structure and is considered to be an engeeniering plastic. Its wide applications include impact resistance, strength, high temperature performance, toughness, load bearing capabilities, dimensional stability, flame retarding capabilities, and excellent optical clarity. Based on these properties they have commercialized as outdoor signs, eye glasses, compact disks, CD-ROM, aircraft windows, automotive windows and instrument panels, food trays and containers, automotive headlamp covers, housings of appliances, and medical devices [18, 19]. It has been found that biopolymer blends possess good thermal stability [20].This study is intended to identify the interaction of polyvinyl alcohol and poly biphenyl dimethyl carbonate to form blends. This study is intended to identify the interaction of polyacrylic acid and poly(biphenyl dimethyl carbonate) to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyacrylic acid and poly (biphenyl dimethyl carbonate) were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and poly (biphenyl dimethyl carbonate) was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and poly(biphenyl dimethyl carbonate) as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing:A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$\Delta G_m = \Delta H_m \quad T\Delta S_m$ (1)

where$\Delta G_m = Gibb's\ free\ energy\ of\ mixing$

$\Delta H_m - Enthalpy\ of\ mixing$

$\Delta S_m = Entropy\ of\ mixing$

$T = Absolute\ temperature$

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always positive for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend suggested that there might be a possibility of a miscible blend at very high temperature.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature. Thus at high temperature there is a possibility to form a miscible blend. The result is in agreement with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this study the coordination number was found to be7.84 +/- 0.05.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperatureof around 1350 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 1350 K).

b. Fragmented metastable regions existedbetween binodals and spinodals, and

c. The two-phase separated regions of immiscibility are bordered by the spinodals.
The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.
When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallizationi.e; slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distributionfor Blend: The generation of different orientations using the pairsmethod may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreasedsignificantly. The maximum frequency was observed for the energy level of around -2.0kcal/mol.

Mixing Energy:A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was high for the temperature range studied. The graph indicated that an increase in temperature further leads to higher mixing energy. This result supported the previous observations. The formation of non homogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSION

The possibility of use of polyacrylic acid and poly(biphenyl dimethyl carbonate) to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible at high temperature. Phase diagram indicated that a single phase can be obtained above 1350 K. The coordination number was found to be 7.84 +/- 0.05 The maximum number of configurations with respect to energy level was found to be -2.0 kcal/mol.The phase separation might make it a porous material to be used as an adsorbent. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is formed with the combination of two or more components. The compatibility of polyvinyl alcohol and polybenzamide were studied to form a miscible blend using Bio-via Materials Studio. The compatibility of the two components was demonstrated based on free energy of mixing, chi parameter, phase diagram and mixing energy. The results indicated that the pair can become compatible only at low temperature. Phase diagram indicated that a single phase can be obtained above 3900 K which was the critical temperature. The coordination number was found to be 6.62 +/- 0.04. The highest number of configurations with respect to energy level was found to be -2.30 kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend , in silico, polyvinyl alcohol, polybenzamide.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working

on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and fraction of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method andthis technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].

The strategy used here for synthesis of poly(Benzamide)s relies on polymer end groups being more reactive than the monomer itself resulting in a kinetically controlled living chain-growth polymerization. Because of good control over the polydispersity and the molecular weight, a number of different polymer [12]. Specially synthesized rigid polybenzamide Nano whiskers of approximately 2000 nm length and 200 nm diameter were reported to increase tensile strength and Young's modulus without sacrificing high strain to-failure. [13]. This study is intended to identify the interaction of polyvinyl alcohol and polybenzamideto form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (DassaultSystemsof France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction

Methodology: Polyvinyl alcohol and polybenzamidewere prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and polybenzamidewas used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polybenzamide as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = *Gibb's free energy of mixing*

ΔH_m = *Enthalpy of mixing*

ΔS_m = *Entropy of mixing*

T = *Absolute temperature*

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is negative at around 160 Kand beyong 500 K and positive for other temperature regeions studied here. The free energy decreases with increase in temperature (upto160 K) as evident from Eq. 1 and free energy increases with increase in temperature after 165 K upto 330 K.Furthet increase in the temperature it decreases gradually. The results indicated that the blend will not lead to a homogeneous mixture for the temperature range 161 K and beyond 500 K. The trend shows a very good compatibility between polyvinyl alcohol and poly polybenzamidewith negative value of mixing energy for the above mentioned temperatures, which may do not lead to form a perfect blend with significantly less effort.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi). Figure 2 shows that the χ value is high for the low temperature range (500 K) .The χ value decreased in temperature. Thus at low temperature there is a possibility to form a miscible blend. This agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 6.62 +/- 0.04.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 3900 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 3900K).

b. Fragmented metastable regions existed between binodals and spinodals, and

c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.

When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.30 kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 6 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy upto 220 K. It also shows that mixing energy gradually increases with decrease in temperature after 220 K upto 410 K and further increase in temperature the mixing energy increases. So, it is very much possible to mix the two components at high temperature with least mixing energy value. The formation ofhomogeneous blend with polyvinyl alcohol as base might help formation of blend with high mechanical strength. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and polybenzamide to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 6.62 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -2.30 kcal/mol.Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

The highest number of configurations with respect to energy level was found to be -1.85kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low cost process.

Keywords: Blend, in silico, polyvinyl alcohol, poly butylene isopthalate.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance

flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11]. poly(butylene isophthalate) (PBI) are of potential interest as low melting temperature thermoplastics with adhesive properties. These materials are frequently referred to as "hot melts".[12].polybutylene isopthalate is a bio-based homo polymer, this polyester belongs to the class of poly (alkylene phthalate).the commercially use of PBI is based open its crystallization capability [13]. This aticle explores the compatibility of mixing of polyvinyl alcohol acid and polybutylene isopthalate in the temperature range of 50 K to 500 K.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyvinyl alcohol and poly butylene isopthalate were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and poly butylene isopthalate was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly butylene isopthalate as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where $\Delta G_m = Gibb's free energy of mixing$

$\Delta H_m = Enthalpy of mixing$

$\Delta S_m = Entropy of mixing$

$T = Absolute temperature$

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive for the temperature regions studied here (50-500). The results indicated that the blend will not lead to a hetrogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very less compatibility between polyvinyl alcohol and poly butylene isopthalate with positive value of mixing energy, which may lead to form a immiscible blend.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicates poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).

Figure 2 shows that the χ value is positive or high for the temperature range studied (50 to 500 K) indicating demixing. The χ value decreased with increase in temperature.Thus at high temperature there is a possibility to form a miscible blend beyond 500K.This agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 9.10 +/- 0.06.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 5 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -1.85kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 6 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy. It also shows that mixing energy gradually increases with increase intemperature upto 390 K, and starts decreasing beyond it. So, it is less possible to mix the two components at any feasible temperature with least mixing energy value. The formation of non homogeneous blend with polyvinyl alcohol as base might help formation of blend with high mechanical strength and porosity. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly butylene isopthalate to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair may have less compatibility at different ranges of temperature. The coordination number was found to be 9.10 +/- 0.06. The maximum number of configurations with respect to energy level was found to be -1.85kcal/mol. Usually components for a blend are identified experimentally. This in silico

study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

This manuscript is intended to explore the miscibility of polyvinyl alcohol and poly (ether sulfone) to form a polymeric blend using Biovia Materials Studio. The combination of two or more components is said to be a blend that may have the potential to display desirable properties. The compatibility of the two components was demonstrated based on the free energy of mixing, chi parameter, phase diagram, and mixing energy. The results indicated that the pair can become compatible only at high temperatures. The phase diagram indicated that a single phase can be obtained above 1280 K which was the critical temperature. The coordination number was found to be 8.70 +/- 0.05. The highest number of configurations with respect to energy level was found to be -2.0 kcal/mol. This study will not only help to determine pairs without performing laboratory experiments but also less time consuming and low-cost process

Keywords: Blend, in silico, polyvinyl alcohol, poly(ether sulfone), biovia material studio.

INTRODUCTION

The blend may be a homogenous or heterogeneous mixture. Blends or composites are the physical combinations of more than one component where components do retain their identity in the mixture.A single material cannot provide multiple anticipated properties. It is desirable to combine different components thereby improving the properties of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus blending is a process that provides an easy pathway to develop a new material by reducing the cost of development of products with preferred properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer. A composite/blend possesses significantly different chemical and physical characteristics from those of its constituent components. In a composite, the constituents remain physically separable and distinct from each other. Usually, a composite is a matrix in which strong and stiff reinforcement is distributed but made of soft

and weaker components [1-3].The upgraded properties of composites are predominantly governed by their microstructure and interaction between matrix and reinforcing materials in the inter-phase region [4, 5].Polymers coupled with carbon-based (graphene, carbon nano-tube) nano-materials [6] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [7] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fireproof materials[8]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [9].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [10]. There are applications of composites in structural engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [11] were developed for the construction of bridges, light rail transit, mining and tunneling, retaining walls, and other waterside buildings. All the above-mentioned examples relied on laboratory experiments. Usually, blends are prepared by trial and error method and this technique is a low cost and less time-consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [12]) has been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness, and whose properties can be controlled by do pant concentrations [13, 14]. The film-forming ability of PVA is widely used in the packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability, and easy process ability [15]. On the other hand, PVA is non-toxic, semi crystalline, hydrophilic, biocompatible, and easily soluble in water [16]. Polyether sulfone (PES) is one of the most important engineering polymeric materials. This polymer is extensively used in membrane separation devices, such as microfiltration and ultra filtration (UF) process in the fields of food, plasma separator, biomedicine, hemodialysis, and water purification, etc.[17-20]. In addition, it displays exceptional thermal, oxidative, and hydrolyticst ability as well as good mechanical and film-forming properties. It has been reported that blending PES with other polymers has addressed the surface physical and chemical properties with respect to improved membrane properties, modifications of the pore structure,etc. [21]. This study is intended to identify the interaction of polyvinyl alcohol and poly(ether sulfone) to form blends. A theoretical approach has been adopted to get the various parameters of blending without chemicals, experiments, and laboratory saving time, money, and energy.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyvinyl alcohol and poly (ether sulfone) were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and poly(ether sulfone)was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly (ether sulfone)as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$\Delta G_m = \Delta H_m \quad T\Delta S_m$ (1)

where ΔG_m = Gibb's free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = Entropy of mixing

T = Absolute temperature

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always positive for the temperature regions studied here (50 K to 500 K). The results indicated that the blend will lead to a heterogeneous mixture for the temperature range of 50 K to 500 K. The trend shows a very less compatibility between polyvinyl alcohol and poly(ether sulfone)with positive value of mixing energy for the above mentioned temperatures, which may lead to form a immiscible blend.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains. Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similar components may lead to a high positive value of χ (chi).

Figure 2 shows that the χ value is high for the low temperature range and low for the high temperature range (500 K) indicating mixing of the components at high temperature. The χ value decreased with increase in temperature. Thus at high temperature there is a possibility to form a miscible blend (beyond 500 K). This agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It is assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be 8.70 +/- 0.05.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:

a. The single-phase miscible region existed above the critical temperature of around 1280 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 1280K).

b. Fragmented metastable regions existed between binodals and spinodals, and

c. The two-phase separated regions of immiscibility are bordered by the spinodals.

The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.

When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.0kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 6 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energy throughout the temperature range.So, it is very much possible to mix the two components at high temperature with high mixing energy value.

The formation of homogeneous blend with polyvinyl alcohol as base might help formation of blend with high mechanical strength. This might have an application as packaging material and adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly(ether sulfone) to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility above 460 K. The coordination number was found to be 8.70 +/- 0.05. The maximum number of configurations with respect to energy level was found to be -2.0 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Usually blend is a combination of two or more mechanism and expected to have homogeneity. In this paper, we have tried to explore the compatibility of polyacrylic acid and poly oxyehylene to form a miscible blend using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, and mixing energy. The results indicated that the pair can have very good compatibility at low to high temperature without any phase separation. The coordination number was found to be 5.23 +/- 0.03 . The highest number of configurations with respect to energy level was found to be -1.7Kal/Mol. This learning will help determine pairs without performing laboratory experiments saving resources, money and time.

Keywords: Blend; Insilico; Polyacrylic acid; Polyoxyethylene

INTRODUCTION

Blends or composite are resources containing more than one part. The components do retain their identity in the combination. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the preferred property. Thus a blend saves time to develop a new material thereby dipping the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in

polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Acrylic acid have a board varity of application in dentistry as denture bases, artificial teeth , denture repair material, maxillofacial appliances for skeletal defects etc.[8] , bone repair [9] dispersing agent, superabsorbent polymer ion replaceresin, etc. [10] Polyacrylic acid is a polyelectrolyte soluble in aqueous media at impartial pH It is used for prepare hydrogels. It is not poisonous and does not reason irritation [11].

The area of high pressure molecular credence polymers deliberate were poly (oxythylene) homo polymers (polyox) with molecular with molecular credence ranging from 4,000,000 to 7,000,000 power characteristics optional fine flowability for these resources and predicted case fulfil importance uniformity irritation[12]. Experiments showed a precise extreme notch of bulge for these resources in equality gastric and shock absorber solution[13]. These polymers bottle sustain the discharge percentage of mutually water-soluble and indecipherable drugs from drug providing system. The soothing molecular burden polymers control a fewer marked sustained-release provoke compare to the eminent molecular authority polymer data (i.e individual with 7,000,000 molecular weight). Intensification in the freedom percentage of the drug. The solubility of the drugs openly influenced the make available rate. Discharge kinetics were evaluated and appeared to be influenced by the molecular import of the polymer, the solubility of medicine, and the ratio of the drug to the polymer in the capsule[14]. Biomodal issue kinetics was exhibit by a amount of furosemide formulation (i.e. F5and F8).

MATERIALS AND METHODS

Software Used: equipment studio module of Biovia software (Dassault Systemes of France) was used for study. The software utilizes appliance learning techniques and standard algorithms to predict the level of communication.

Methodology: Polyacrylic acid and poly oxyehylene were prepared using the build menu of resources Studio. The construction of the mechanism were optimized using the components were used in blends->estimate menu of Materials studio. Polyacrylic acid was used as the base and poly oxyethylene used as screen. After calculation the blends->analysis menu of Materials studio was used to make various data. The data were analyze and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this effort the use of polyacrylic acid and poly acrylic acid potential mechanism of a blend was analyzed by Biovia resources Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

Where ΔG_m = Gibbs free energy of mixing

ΔH_m = Enthalpyofmixing
ΔS_m = Entropyofmixing
T = absolute temperature

The value of $T\Delta S_m$is for all time positive in case of a blend since there is an increase in the entropy on addition. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic involvement to free energy exceed the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in addition is always positive or greater than zero for the temperatures studied. The free energy decreases with increase in temperature as marked from Eq. 1. The results indicated that the blend is heterogeneous mixture for the temperature range studied (50 to 500 K). The trend show a very good compatibility among polyacrylic acid and poly oxyehylene with positive value of mixing energy.

Chi Parameter: The Flory–Huggins χ parameter describe the excess free energy of addition and helps to explain phase performance for polymer blends and block co polymers. For polymers which are not chemically similar, a important mismatch in cohesive energy density leads to a high χ value and, hence, a greater heavy force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymers having small cohesive energy variation χ value is probable to be small. However, there is a chance of demixing for adequately long chains.Architectural and geometric differences between the components check them in a combination from occupying the same configurations experience in the pure phase. Polymer field theory can predict that a difference in chain stiffness for chemically like components may lead to a high positive value of χ (chi).

Figure -2 shows that the superior inner self worth for the high temperature breadth international (50 to 500) indicating exact scanty mixing. The essence merit diminution with an intensification in heat up to 480K and the price practically remained unbroken with auxiliary increase in temperature. There is a lesser odd of identical incorporation with such amount of essence which agrees with the free energy of addition for the combination.

Coordination Number: The coordination number a_{ij} is the figure of molecules of type *j* that can be packed around a single molecule of type *i.* The coordination number was calculate for every of the possible molecular pairs involved in molecular simulation. The "Blends" module of equipment studio differed from the Flory-Huggins model and used an off-lattice estimate. It assumed that molecules are not set on a regular lattice as probable in the original Flory-Huggins theory. The coordination number is significant only when the mechanism of the binary blend have like volumes or surface areas. It is hard to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this learning the coordination number was found to be5.23 +/- 0.03.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:
a. The single-phase miscible region existed above the critical temperature of around 800 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 800 K).
b. Fragmented metastable regions existed between binodals and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.
The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.

When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains.

On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blends: The making of something else orientation via the pairs technique may be in the lead to configuration of unreliable energy levels. Figure 4 shows the plot of frequency(PE) against energy levels. It shows the distribution is a small piece irregular and close to is a long, low energy extension. The come to of configuration with energy higher than the tip set great store by decreased significantly. The maximum frequency was experimental for the energy level of around -1.7Kal/Mol.

Mixing Energy: A little value of mixing energy can favor the addition process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperature increased the mixing energyfigure-5 shows that the combination energy for the system was minor for the passion collection studied. The chart indicated that an encourage in heat enlarged the combination energy. It in addition shows that assimilation energy will be no to around 210K, and the cost increasingly increase up to 9.6Kal/Mol at a temperature of 345K. However the amalgamation energy all over again reduces beyond the high temperature 345K. So, it is extremely a great deal likely to combine the two workings at any reasonable heat with slightest assimilation energy value. The formation of nonhomogeneous combine with polyacrylic acid as centre power good thing formation of balance with senior porosity such as hydrogel.

CONCLUSION

The possibility of use of polyacrylic acid and poly acrylic acid to form a homogeneous blend was explored using Biovia resources Studio. The compatibility was analyze based on free energy of addition, chi parameter and mixing energy. The results indicated that the pair can have less compatibility at different ranges of temperature. The coordination number was found to be 5.23 +/- 0.03 The maximum number of configurations with respect to energy level was found to be -1.7Kal/Mol Usually components for a blend are identified experimentally. This in silico study will help determine mechanism of a blend without performing laboratory experiments economy equipment, currency and time.

ABSTRACT

Polyacrylic acid is a weak anionic polelectrolyte whose degree of ionization is pH dependant solution. In its non ionized form at low pHs, PAA may associate with various non ionic polymers. A blendis composition of two or more components and it is desirable to have homogeneityin a blend. In this article, we have tried to explore the compatibility of polyacrylic acid andPoly-1,2-*α*-D-galactoseto form a miscible blend using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, and mixing energy. The results indicated that the pair can have very good compatibility at low to high temperature without any phase separation. The coordination number was found to be 6.46 +/- 0.03. The highest number of configurations with respect to energy level was found to be -2.1 kcal/mol. This study will help in determining the pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, polyacrylic acid, Poly-1,2-*α*-D-galactose, in silico, Biopolymer

INTRODUCTION

Poly acrylic acid is a polyelectrolyte which is soluble in aqueous media at neutral pH due to the ionization of the pendent carboxyl side chains. Blends or composites are materials containing more than one component. The components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nanomaterials have the ability to improve the properties of polymeric materials. Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancywithout increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7] have been used to identify compatible pairs.Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair[9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10].Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation [11].

Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12].Glucose forms glycosidic bonds with itself, galactose to produce to nutritionally important disaccharides [13]. It has been found that biopolymer blends possess good thermal stability[14].This study is intended to identify the interaction of polyacrylic acid and Poly-1,2-α-D-galactoseto form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyacrylic acid and Poly-1,2-α-D-galactosewere prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and Poly-1,2-α-D-galactosewas used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and Poly-1,2-α-D-galactoseas potential components of a blend was analyzed using Biovia Materials Studio.

Free energy of mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$\Delta G_m = \Delta H_m \quad T\Delta S_m$ (1)

where $\Delta G_m = Gibbs\ free\ energy\ of\ mixing$

$\Delta H_m = Enthalpy\ of\ mixing$

$\Delta S_m = Entropy\ of\ mixing$

T = Absolutetemperature

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$\Delta H_m < T\Delta S_m$ (2)

Figure 1 shows that the free energy involved in mixing is always negative or less than zero for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will absolutely lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyacrylic acid and Poly-1,2-α-D-galactosewith negative value of mixing energy, which may lead to form a perfect blend with significantly less effort.

CHI Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi).

Figure 2 shows that the χ value is very small or negativefor the temperature range studied (50 to 500 K) indicating very good mixing. The χ value increased with an increase in temperature upto500 K. There is a very good possibility of homogeneous mixing with such small value of χ which agrees with the free energy of mixing for the blend.

Coordination number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this study the coordination number was found to be6.46 +/- 0.03.

Energy distribution for blend: The generation of different orientations using the pairsmethod may lead to configurations of varying energy levels. Figure 3 shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreasedsignificantly. The maximum frequency was observed for the energy level of around -2.1kcal/mol.

Mixing energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 4 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperatureincreased the mixing energy. It shows that mixing energy gradually decreasingstarting from 50k up to 230K. However the mixing energy again increasesfrom 240K. So,it is very much possible to mix the two components at any feasible temperature with least mixing energy value. The formation of non homogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSION

The possibility of use of polyacrylic acid and Poly-1,2-α-D-galactoseto form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 6.46 +/- 0.03. The maximum number of configurations with respect to energy level was found to be-2.1 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

INTRODUCTION

Biopolymers contain monomeric units that are covalently bonded to form larger structures. Biopolymers based on synthetic are used too manufacture many products of human use. Poly acrylic acid is a polyelectrolyte which is soluble in aqueous media at neutral pH due to the ionization of the pendent carboxyl side chains. Blends or composites are materials containing more than one component. The components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancywithout increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio[7] have been used to identify compatible pairs. Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair[9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10]. Polyacrylic acid is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation[11].

Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12].Glucose forms glycosidic bonds with itself, galactose to produce to nutritionally important disaccharides [13]. It has been found that biopolymer blends possess good thermal stability[14].This study is intended to identify the interaction of polyacrylic acid and poly-1,2-β-D-galactoseto form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyacrylic acid and poly-1,2-β-D-galactosewere prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyacrylic acid was used as the base and poly-1,2-β-D-galactosewas used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acid and poly-1,2-β-D-galactoseas potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m \quad T\Delta S_m \qquad (1)$$

where $\Delta G_m - Gibb\,s\,free\,energy\,of\,mixing$

$\Delta H_m = Enthalpy\,of\,muxing$

$\Delta S_m = Entropy\,of\,mixing$

$T = Absolute\,temperature$

The value of $T\Delta S_m$is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_malways depends on the value of the enthalpy of mixingΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive or more than zero for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend will absolutely lead to a homogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyacrylic acid and poly-1,2-β-D-galactose with positive value of mixing energy, which may lead to form a perfect blend with significantly less effort.

Chi parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi).

Figure. 2 shows that the χ value is very small in decreasing orderfor the temperature range studied (50 to 500 K) indicating very good mixing. The χ value gradually decreased in increase in tempreturestarting from 50K up to 500K. There is a very good possibility of homogeneous mixing with such small value of χ which agrees with the free energy of mixing for the blend.

Coordination number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size.In this study the coordination number was found to be7.41 +/- 0.04.

Energy distribution for blend: The generation of different orientations using the pairsmethod may lead to configurations of varying energy levels. Figure 3.shows the plot of frequency (P(E)) against energy levels. It shows that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreasedsignificantly. The maximum frequency was observed for the energy level of around -2.0kcal/mol.

Mixing energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 4 show that the mixing energy for the system was gradually increases with increase in temperature. The graph indicated that an increase in temperatureincreased the mixing energy. It also shows that mixing energy always positive from 50to 500 K, and the value gradually increases up to 26kcal/mol at a temperature of 500K. So, it is very much possible to mix the two components at any feasible temperature with least mixing energy value. The formation of nonhomogeneous blend with polyacrylic acid as base might help formation of blend with higher porosity such as hydrogel. This might have an application as adsorbent.

CONCLUSION

The possibility of use of polyacrylic acid and poly-1,2-β-D-galactoseto form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have very good compatibility at different ranges of temperature. The coordination number was found to be 7.41 +/- 0.04. The maximum number of configurations with respect to energy level was found to be -2.0 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time as well.

ABSTRACT

Generally blend is a mixture of two or more components and expected to have homogeneity. In this paper, we have tried to explore the compatibility of polyvinyl alcohol and poly(biphenyl dimethyl carbonate)to form a miscible blend using Biovia Materials Studio. The compatibility of the two components was studied based on free energy of mixing, chi parameter, and mixing energy. The results indicated that the pair can have very good compatibility at low to high temperature without any phase separation. The coordination number was found to be 8.50 +/- 0.05. The highest number of configurations with respect to energy level was found to be -2.5 kcal/mol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, in silico, polyvinyl alcohol, poly(biphenyl dimethyl carbonate), phase diagram

INTRODUCTION

Blends or composites are materials containing more than one component. The components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in

polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].

Poly(biphenyl dimethyl carbonate) has an amorphous structure and is considered to be an engeeniering plastic. Itswide applicationsinclude impact resistance, strength, high temperatureperformance, toughness, load bearing capabilities, dimensional stability, flame retarding capabilities, and excellent optical clarity.Based on these properties they have commercialized asoutdoor signs, eye glasses, compact disks, CD-ROM, aircraft windows, automotive windows and instrument panels, food trays and containers, automotive headlamp covers, housings of appliances, and medical devices[12, 13]. It has been found that biopolymer blends possess good thermal stability [14].This study is intended to identify the interaction of polyvinyl alcohol and poly(biphenyl dimethyl cabonate)to form blends.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: Polyvinyl alcohol and polypoly(biphenyl dimethyl cabonate)were prepared using the build menu of Materials Studio. The structure of the components were optimized using the components were used in blends->calculation menu of Materials studio. Polyvinyl alcohol was used as the base and poly(biphenyl dimethyl carbonate)was used as screen. After calculation the blends->analysis menu of Materials studio was used to generate various data. The data were analyzed and the compatibility of the components to form a blend was analyzed.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly(biphenyl dimethyl carbonate)as potential components of a blend was analyzed using Biovia Materials Studio.

Free Energy of Mixing: A blend is said to be miscible if it is homogeneous. A negative value of free energy of mixing indicates that mixing is spontaneous and can lead to a homogeneous blend. Thermodynamic analysis suggests that

$$\Delta G_m = \Delta H_m - T\Delta S_m \quad (1)$$

where ΔG_m = Gibbs free energy of mixing

ΔH_m = Enthalpy of mixing

ΔS_m = Entropy of mixing

T = Absolute temperature

The value of $T\Delta S_m$ is always positive in case of a blend since there is an increase in the entropy on mixing. Therefore, the sign of ΔG_m always depends on the value of the enthalpy of mixing ΔH_m. The components can mix to form a miscible blend only if the entropic contribution to free energy exceeds the enthalpic contribution, i.e.,

$$\Delta H_m < T\Delta S_m \quad (2)$$

Figure 1 shows that the free energy involved in mixing is always positive and greater than zero for the temperatures studied. The free energy decreases with increase in temperature as evident from Eq. 1. The results indicated that the blend is a heterogeneous mixture for the temperature range studied (50 to 500 K). The trend shows a very good compatibility between polyvinyl alcohol and poly(biphenyl dimethyl carbonate) with positive value of mixing energy, which indicates that high energy is required to form a homogenous mixture.

Chi Parameter: The Flory–Huggins χ parameter describes the excess free energy of mixing and helps to explain phase behavior for polymer blends and block copolymers. For polymers which are not chemically similar, a significant mismatch in cohesive energy density leads to a high χ value and, hence, a greater driving force for phase separation. Thus a high value of χ for chemically dissimilar polymers indicate poor mixing. For chemically similar polymershaving small cohesive energy difference χ value is expected to be small. However, there is a chance of demixing for sufficiently long chains.Architectural and geometric differences between the components prevent them in a mixture from occupying the same configurations experienced in the pure phase. Polymer field theory can predict that a mismatch in chain stiffness for chemically similarcomponentsmaylead to a high positive value of χ (chi). The higher/positiveχ value for the temperature range studied (50 to 500 K) indicating very poor mixing (Figure 2). The χ value decreased with an increase in temperature upto260K and the value slightly increased and remained constant with further increase in temperature.There is a lesser possibility of homogeneous mixing with such value of χ which agrees with the free energy of mixing for the blend.

Coordination Number: The coordination number Z_{ij} is the number of molecules of type *j* that can be packed around a single molecule of type *i*. The coordination number was calculated for *each* of the possible molecular pairs involved in molecular simulations. The "Blends" module of Materials studio differed from the Flory-Huggins model and used an off-lattice calculation. It assumed that molecules are not arranged on a regular lattice as expected in the original Flory-Huggins theory. The coordination number is significant only when the components of the binary blend have similar volumes or surface areas. It is difficult to apply the pairs method in defining a coordination number for a binary system in which the components are not similar in size. In this study the coordination number was found to be8.50 +/- 0.05.

Phase Diagram: The compatibility of binary mixtures can be visualized by phase diagrams. Figure 3 shows the phase diagram for the two components of the blend. There are three regions of different degree of miscibility:
a. The single-phase miscible region existed above the critical temperature of around 1180 K. This value supported the fact that a single phase blend can be formed at a high temperature (higher than 1180 K).
b. Fragmented metastable regions existed between binodals and spinodals, and
c. The two-phase separated regions of immiscibility are bordered by the spinodals.
The binodals separated miscible (one-phase) and metastable region, while the spinodals separated the metastable and two-phase region.

When the system enters from single-phase region to the metastable region, the phase separation usually occurs by the mechanism of resembling crystallization i.e, slow nucleation followed by growth of the phase separated domains. On the other hand, when the system jumps from a single-phase into the spinodal region of immiscibility the phases separate spontaneously by a mechanism called spinodal decomposition.

Energy Distribution for Blend: The generation of different orientations using the pairs method may lead to configurations of varying energy levels. Figure 4 shows the plot of frequency (P(E)) against energy levels. It shows

that the distribution is somewhat asymmetrical and there is a long, low-energy tail. The number of configurations with energy higher than the peak value decreased significantly. The maximum frequency was observed for the energy level of around -2.5kcal/mol.

Mixing Energy: A small value of mixing energy can favor the mixing process. Thus, the temperature at which the mixing energy is low can be chosen for mixing. Figure 5 shows that the mixing energy for the system was small for the temperature range studied. The graph indicated that an increase in temperatureincreased the mixing energy. It also shows that mixing energy positive and decreases up to210 K, and the value gradually increases beyond temperature of220 K.This indicates the less possibility of mixing of these components in the temperature range of 50-500 K. The formation of non homogeneous blend with polyvinyl alcohol as base might help formation of blend with higher porosity such as hydro gel. This might have an application as adsorbent.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly(biphenyl dimethyl carbonate)to form a homogeneous blend was explored using Biovia Materials Studio. The compatibility was analyzed based on free energy of mixing, chi parameter and mixing energy. The results indicated that the pair can have less compatibility at different ranges of temperature. The coordination number was found to be 8.50 +/- 0.05. The maximum number of configurations with respect to energy level was found to be -2.5 kcal/mol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and and polybutylene isopthalate to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time

Keywords: Biovia, polyvinyl alcohol , polybutylene isopthalate

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].poly(butylene isophthalate) (PBI) are of potential interest as low melting temperature thermoplastics with adhesive properties. These materials are frequently referred to as "hot melts"[12].Polybutylene isopthalate is a bio-based homo polymer, this polyester belongs to the class of poly (alkylene phthalate).the commercially use of PBI is based open its crystallization capability [13].

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polybutylene isopthalate were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and Poly butylene isopthalate as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Permeability of gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium. Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of vinyl alcohol.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of vinyl alcohol. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly butylene isopthalateto form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio

and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Acrylic polymers have a wide variety of applications in dentistry as denture bases, artificial teeth, denture repair materials, maxillofacial appliances for skeletal defects etc. [8], bone repair [9], dispersing agent, superabsorbent polymer, ion-exchange resin, etc.[10]. Polyvinyl alcohol is a polyelectrolyte soluble in aqueous media at neutral pH It is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. poly(butylene isophthalate) (PBI) are of potential interest as low melting temperature thermoplastics with adhesive properties. These materials are frequently referred to as "hot melts".[12]. poly(butylene isophthalate) is a bio-based homo polymer, this polyester belongs to the class of poly (alkylene phthalate).the commercially use of PBI is based open its crystallization capability [13]. In this study the themal and dielectric properties of a blend between polyvinyl alcohol and poly(butylene isophthalate) are explored by using Biovia material studio.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction

Methodology: The structures of polyvinyl alcohol and poly (ethylene isophthalate) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly (ethylene isophthalate) as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite decreases with increase in mass fraction of vinyl alcohol.

Thermal conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Dielectric constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly (ethylene isophthalate) to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the heat capacity and thermal conductivitydecreased with increase in mass fraction of vinyl alcohol whereas the dielectric constant decreased with it. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and polybutyleneisopthalate to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol except Poisson ratio.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend, Polyvinyl alcohol, Polybutyleneisopthalate

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].poly(butylene isophthalate) (PBI) are of potential interest as low melting temperature thermoplastics with adhesive properties. These materials are frequently referred to as "hot melts".[12]. poly(butylene isophthalate) is a bio-based homo polymer, this polyester belongs to the class of poly (alkylene phthalate).the commercially use of PBI is based open its crystallization capability [13].

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polybutyleneisopthalate were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polybutyleneisopthalate as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polybutyleneisopthalate to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol except Poisson ratio. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Generally, blend is a mixture of two or more components and expected to have homogeneity. In this paper, we have tried to explore the compatibility of polyvinyl alcohol and poly (biphenyl dimethyl carbonate) to form a miscible blend using Biovia Materials Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

INTRODUCTION

Blends or composites are materials containing more than one component. The components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in

polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].

Poly(biphenyl dimethyl carbonate) has an amorphous structure and is considered to be an engeeniering plastic. Its wide applications include impact resistance, strength, high temperature performance, toughness, load bearing capabilities, dimensional stability, flame retarding capabilities, and excellent optical clarity. Based on these properties they have commercialized as outdoor signs, eye glasses, compact disks, CD-ROM, aircraft windows, automotive windows and instrument panels, food trays and containers, automotive headlamp covers, housings of appliances, and medical devices [12, 13]. It has been found that biopolymer blends possess good thermal stability [14].This study is intended to identify the interaction of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) to form blends. This study is intended to explore the mechanical properties of the blends developed by mixture of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) using synthia tool.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction

Methodology: The structures of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases with increase in mass fraction of vinyl alcohol.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases with increase in mass fraction of vinyl alcohol.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases with increase in mass fraction of vinyl alcohol.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. ABSTRACT

A blend is created bythe combination of two or more components. The compatibility of polyvinyl alcohol andpoly ethylene Terephthalate were study to form a miscible blend using Biovia Materials Studio. The mechanical properties of the composite to be studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The consequences indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, currency and time

Keywords: synthia, in silico, polyvinyl alcohol, polyethylene terephthalate.

INTRODUCTION

Blends or composites to be formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to mix dissimilar components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilize the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of improvement of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material customized polymers paved the way to multi useful materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire evidence materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy lacking increasing the weight [4]. Researchers have emphasize on synthesis and production of lightweight composite material having high strength important for enhancing fuel efficiency in the

field of transport [5]. There are application of composites in structural Engineering due to high strength to weight ratio and resistance to decay. Thus, glass fiber durable polymers, latex polymer cementitious composites [6] were developed for building of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mention example relied on laboratory experiments. Usually blends are prepared by test and fault method andthis method is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico move toward to develop new blends. Software (Materials Studio [7]) has been used to identify well-matched pairs. Among the a mixture of polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, simple film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is extensively used in covering industry to form strong polymeric films. It is because of their high mechanical power, environmental stability and easy processability [10]. On the other hand, PVA is poisonous, semicrystalline, hydrophilic, biocompatible and simply soluble in water [11].

The consumption of plastics in Western Europe is of 38 million tonnes per year, the majority of which are used in the production of plastic packaging, household and domestic products, electrical and electronic goods [12]. There is also significant consumption of plastics for the structure and construction industry and automotive industry. The two main types of plastics are thermoplastics, which soften when heated and harden again when cooled, and thermosets, which harden by curing and cannot be re-moulded. About 80 % of plastics used in Western Europe are thermoplastics [13].For many waste landfills is the largest route for disposal throughout the countries of Europe. For some countries, including Lithuania, more than 60 % of municipal solid waste is disposed of to landfill [14]. Plastics make up high proportion of waste that volume and range used increases dramatically. Although plastics make up between 5 wt.% and 15 wt.% of municipal solid waste it comprises 20 % – 30 % of the volume [13]. Most plastics are non-degradable and take a long time to decompose, possibly up to hundreds of years – although no-one knows for certain as plastics have not existed for long enough, when they are landfilled. It is estimated that only about 50 % of the plastics produced in Western Europe each year are available for collection and recycling [12 – 14].

According to the experts from Kaunas University of Technology in Lithuania plastics reach about 82 thousands tones of municipal solid waste in 2004. It comprised about 24 kg for one inhabitant [15]. Waste recycling in Lithuania increases constantly andduring 2000–2006 it ranges between 20 – 35 thousand tonnes per year [16]. According to the Environmental Protection Agency (EPA) "recycling" is considered to be processing of waste to make new article. There are divided three distinct approaches to the recycling of post-consumer plastic materials: 1) it could be reused directly; 2) undergo physical reprocessing, for example, grinding, melting and reforming; 3) be subjected to chemical treatment, when components are isolated and reprocessed for use in manufacture. A new widespread nomenclature of recycling was adopted by EPA. Primary recycling involves the use of pre-consumer industrial scrap and salvage, while physical reprocessing refers as secondary recycling and chemical processing as tertiary recycle [16].

MATERIALS AND METHODS

Software Used: equipment studio part of Biovia software (Dassault Systemes of France) was used for analysis. The software utilize machine study techniques and normal algorithms to predict the level of interaction.

Methodology: The structure of polyvinyl alcohol and poly ethylene Terephthalatewere fed to the synthia menu of equipment Studio. It was then run for different weight fractions of the mechanism. Different property of the composite was displayed in a tabular form. The values to be used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

The use of polyvinyl alcohol andpoly ethylene Terephthalate as potential mechanism of a composite was analyze using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-define correlation (advanced quantitative structure-property relationships) to estimate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. accordingly, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic relations that give rise to it. However, the main shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculate.To overcome this limitation, the technique implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from diagram theory are employed. The mechanical properties of the composite were premeditated based on size module, Bulk modules, Youngs modulus, Poission ratio and brittle stress fracture.

Bulk Modulus : The Bulk modulus of a substance is a measure of how resistance to compression that substance is. It is defined as the ratio of the infinitesimal pressure increase to the resulting relative to decrease of the volume. Figure 1 shows that the form modulus of the composite increase linearly with fuel in main part of poly vinayl alcohol.

Shear Modulus: The shear modulus is defined as the ratio of shear stress to shear strain. It is also known as modulus of rigidity. Figure 2 says that the modulus of rigidity of the composite increase with increase in ,ass fraction of polyvinayl alcohol

Young's Modulus: Young modulus, is a mechanical property that measures the stiffness of a solid material. Figure 3 shows that the Young's modulus of the composite increase with increase in mass fraction of poly vinayl alcohol

Poisson Ratio: Poisson's ratio is the ratio of transverse contraction strain to longitudinal extension strain in the direction of stretching force. Figure 4 shows that the Poisson ratio of the composite increase linearly with increase in mass fraction of poly acrylic acid.

Brittle Fracture Stress : A brittle fracture is the fracture of a metallic object or other material with appreciable prior plastic deformation. It is a break in a brittle piece of metal that failed because stress exceeded cohesion Figure 5 shows that the brittle fracture stress of the composite increase in increase in mass fraction of poly vinayl alcohol.

CONCLUSION

The preference of take advantages of polyacryalic acid and poly oxyethylene to a found a identical was explored by Biovia equipment studio. The organization of the balance was analyzed with think a lot of mechanical properties. The mechanical properties were considered based on substance modules, Young's modulus, Bulk modulus, Poisson ratio, shear modulus, brittle fracture. the result indicated that the values of all the properties increase and increase with increase in mass fraction of polyvinayl alcohol. This in silico revision will comfort govern mechanism of a mix together without the stage laboratory experiments economy materials, money and time.

ABSTRACT

Polymeric blends are useful in preparing hybrid materials with improved properties, related to packaging application. Blends are basically prepared with two or more than two polymers. The improvements in physical and chemical property of these blends are strongly depicted through their molecular level of interactions and therefore, guided by their mixing compatibility or homogeneity of the blends. To get the desired mechanical and gas barrier performance of the prepared poly (biphenyl dimethylcarbonate) (PC) based packaging material, the optimum composition of PC with polydimethylsiloxane (PDMS) was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density was found to increase with the increase in poly (biphenyl dimethylcarbonate) fraction or lowing of polydimethylsiloxane fraction. The permeability properties of the blend were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of biphenyl dimethyl carbonate. This in-silicostudy helps us to determine the best composition of the blend without performing laboratory experiments which saves valuable time and wastage of raw materials too

Keywords: Gas permeability, Blend, in-silico analysis, Compatibility, Packaging

INTRODUCTION

Polymeric blends are usually offered improved physical and chemical properties like thermal, mechanical, gas barrier and biodegradability [1]. These properties are the prime interest for the researchers to design best packaging material. Gas permeability is sometimes offered as essential criterion to design the polymer for biomedical and industrial utilization. For instance, polymers with high barrier properties, i.e. low permeability, are mandatory for food packaging applications to prevent loss of aroma, color and food-value and to slow down spoilage [2]. Apart

from this food packaging application; there are lots of other applications which require the polymers to have high, low or tailored permeability like, filters and membranes for gas or liquid separation [3], protective coatings (e.g., paints and varnishes) [4], polymer coatings for controlled drug release [5] and water desalination [6].The permeability of liquids and gases through polymer membranes (plastic films) may be happened by either a temperature or pressure gradient, or by concentration gradient or external force field. The ''solution-diffusion'' mechanism is generally used to depict the pathway of gas permeation. It involvesthree steps. In the first step absorption of small molecules is happened into the membrane at the side of higher gradient (concentration, pressure, etc). On the other hand, second step involves the molecular diffusion through the membrane and the final step is related to desorption of those molecules from the membrane at the opposite side of lower gradient. The gas permeability in a polymer is generally varied with the nature of polymer and permeates. It may be accounted due to various degree of crystallinity and porosity of the polymers along with surface functionality (hydrophilic/ hydrophobic groups).

The main aim of combining polymeric materials is to achieve the desired quality of the material. Among various polymers, poly (biphenyl dimethylcarbonate) (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical strength[7]. As a resultof these excellent properties, PC has been largely employed in electronic and electronic appliances along with automotive industry, having an annual production of 6 million tons. Recent report by Behboudiet. al. [8] shows thatPC is blended withpolyvinyl chloride (PVC)to preparethe ultrafiltration membrane for water purification. On the other hand, PC is also blended with poly(vinylidene fluoride) (PVDF) to prepare mechanically strong multicomponent nanocomposites with nanostructural reinforcement of graphenenanoplates, carbon nanotube, and organically modified montmorillonite [9]. In another recent report Wen et al. reinforced the graphene plates into blend of polybutyleneterethalate and polycarbonate [10] to obtain electrical and thermal conductive materials. The unique material, formed from the blend of PC with polystyrene is also reported to sense organic vapours with incorporation of multiwalled carbon nanotubes (MWCNTs) [11]. Polycarbonate blended polysulfone material is recently observed to have improved thermal and mechanical properties[12].

Therefore,investigationof blending compatibility of polycarbonate with other polymer is the urgent need of current research to develop advanced functional materials. All the above mentioned examples relied on laboratory experiments. Usually, preparation of homogeneous blend in wet-lab condition, requires huge time and wastage of materials which can be minimized by in-silico approach through material studio [13] of "Biovia" software. In present context, we are focusing to optimize the homogeneous blend composition of poly (biphrnyl dimethylcarbonate) (PC) with polydimethylsiloxane (PDMS) in terms of gas permeability. Polydimethylsiloxane is a polymeric organosilicon compound, especially known for its unordinary rheological practices. Also it is optically clear, non-harmful and non-combustible. Polydimethylsiloxane (PDMS) shows wide applications like contact focal points, clinical gadgets and advanced elastomer materials. It is likewise utilized in creation of ointments and heat-resistant tiles. As of late, Adreeset. al. [14] prepared the PDMS based mixed layers with polyvinyl chloride-co-vinyl acetic acid derivative (PVCA) for CO_2seperation. Polydimethylsiloxane is likewise utilized in biomedical application like maxillofacial prosthetics, fake veins and articular ligament substitution, when it is mixed with poly (ether) ketone (PEEK) [15]. Consequently, the present in-silico approach towards examination of gas permeability of the blend having various composition of poly (biphenyldimethyl carbonate) (PC) and polydimethylsiloxane (PDMS) might be used to upgrade the sythesis to create attractive advanced materials for packaging applications.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of poly (biphenyl dimethylcarbonate) and polydimethylsiloxane (PDMS) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of poly (biphenyl dimethylcarbonate) on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly(biphenyl dimethylcarbonate)and polydimethylsiloxaneas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite increasedlinearly with increase in mass fraction of biphenyl dimethyl carbonate.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite increased linearly with increase in mass fraction of biphenyl dimethyl carbonates. Therefore, prepared materials offered compact structures which may not be suitable for adsorption, but suitable for packaging material, where high gas barrier property is required.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygenthrough the hybrid polymer decreased with increase in mass fraction of biphenyl dimethyl carbonate. On the other hand, Figure 4 shows that the permeability of nitrogenthrough the hybrid polymer is decreased with increase in mass fraction of biphenyl dimethyl carbonate. Same pattern is also observed in case of permeability of CO_2 through the hybrid polymer. Figure 5, shows that the permeability of carbon dioxidethrough the hybrid polymer decreased with increase in mass fraction of biphenyl dimethyl carbonate. Thus the results indicated that an increase in biphenyl dimethyl carbonate fraction reduced the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of poly (biphenyl dimethylcarbonate)and polydimethylsiloxaneto form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume and density decreased with increase in biphenyl dimethyl carbonate fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of

biphenyl dimethyl carbonate. Usually components for a blend are identified experimentally. This in-silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Generally, blend is designed with the mixing of two or more components. The change in properties of polyacrylic acid and poly-1, 2-α-D-galactosewas studied in a miscible blend using Biovia Materials Studio. The permeability properties of composition of the blend were studied so that it can be used in different potential application. The molar volume and density of the blend was observed to be decreased with increase in acrylic acid fraction. The gas permeability properties of the composite were observed based on permeability of oxygen, nitrogen and carbon dioxide. From the results, it was noticed that the permeability for all the gases such as oxygen, nitrogen and carbon dioxide are increased with increase in mass fraction of acrylic acid. This technique will be useful us to determine pairs without performing laboratory experiments and also without using materials and money.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. It is important to develop a single material with the required property for significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Therefore, utilizing blend gives several benefits as it reduces the cost of development of products with required properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material assisted polymer composites and functionalized polymer are used in various environmental applications [1]. Polymers assisted with carbon based (graphene, carbon quantum dot, carbon nano-tube) nano-materialshave drawn special attention towards use in various applications. Researcher has also synthesized natural

fiber based polymer composites to enhance mechanical properties and water resistance [2]. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Acrylic acid is an organic compound which contains a vinyl group attached to carboxylic acid.It can be used in various purpose such as dispersing agent,artificial teeth and bone repair because of its biocompatibility, biodegradability nature and low toxicity [8-10]. Polyacrylic acid as water soluble polymer have been given as special attention because it can be applied in various applications such as ion exchange, efficient corrosion inhibitor and capacitorsand also it is used for preparing hydrogels. It is not toxic and does not cause irritation [11]. Researchers have used D-galactose in combination with other materials to different applications [12]. Poly-1, 2-α-D-galactose has been reported to be used in Curtius reaction. This study is intended to find out the change of gas permeability value of blend of polyacrylic acid and poly-1, 2-α-D-galactosewith different proportions.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyacrylic acid and poly-1, 2-α-D-galactose werefed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acid on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work, the use of polyacrylic acidandpoly-1, 2-α-D-galactoseas potential components of a composite was analyzed using Biovia Materials Studio.Biovia Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases with increase in mass fraction of acrylic acid.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygenthrough the composite increases with increase in mass fraction of acrylic acid.

Figure 4 shows that the permeability of nitrogenthrough the composite increases with increase in mass fraction of acrylic acid. Figure 5 shows that the permeability of carbon dioxidethrough the composite increases with increase in mass fraction of acrylic acid.

CONCLUSION

The gas permeability properties of blend which is formed from polyacrylic acidand poly-1, 2-α-D-galactoseare analyzed using Biovia Materials Studio. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were noticed based on permeability of oxygen, nitrogen and carbon dioxide. From the results, it was observed that the permeabilityfor all the gases increased with increase in mass fraction of acrylic acid. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments without use of chemicals.

ABSTRACT

A blend is a mixture of more than one components. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and poly-1,2-β-D galactose to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Silico, polyvinyl alcohol, poly-1,2-β-D galactose.

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].

Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12]. It has been found that biopolymer blends possess good thermal stability [13].This study is intended to identify the interaction of polyvinyl alcohol and poly-1,2-β-D galactose to form composite.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction

Methodology: The structures of polyvinyl alcohol and poly-1,2-β-D galactose were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1,2-β-D galactose as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 show that the permeability of oxygenthrough the composite decreases with increase in mass fraction of vinyl alcohol.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of vinyl alcohol. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1,2-β-D galactose to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

A blend is a mixture of more than one components. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and polyabenzamideto provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: gas permeability properties,Silico, polyvinyl alcohol, polybenzamide.

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].

The strategy used here for synthesis of poly(benzamide)s relies on polymer end groups being more reactive than the monomer itself resulting in a kinetically controlled living chain-growth polymerization. Because of good control over the polydispersity and the molecular weight, a number of different polymer [12].Polybenzamidehave been reported to be used in Curtius reaction. This study is intended to identify the interaction of polyvinyl alcohol and polybenzamide to form composite.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polybenzamide were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polyabenzamide as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulphur, fluorine, chlorine, bromine.

Molar Volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite decreases linearly with increase in mass production of vinyl alcohol.

Permeability of Gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the membrane. Figure 3 show that the permeability of oxygenthrough the composite decreases with increase in mass fraction of vinyl alcohol.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass production of vinyl alcohol. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and polyabenzamideto form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume and density decreased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

Usually, blend is a mixture of two or more components and expected to have homogeneity. In this paper, we have tried to explore the compatibility of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) to form a miscible blend using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Gas Permeability Properties, Polyvinyl Alcohol, Biphenyl Dimethyl Carbonate.

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11]. Poly(biphenyl dimethyl carbonate) has an amorphous structure and is considered to be an engeeniering plastic. Its wide applications include impact resistance, strength, high temperature performance, toughness, load bearing capabilities, dimensional stability, flame retarding capabilities, and excellent optical clarity. Based on these properties they have commercialized as outdoor signs, eye glasses, compact disks, CD-ROM, aircraft windows, automotive windows and instrument panels, food trays and containers, automotive headlamp covers, housings of appliances, and medical devices [12, 13]. It has been found that biopolymer blends possess good thermal stability [14]. This study is intended to explore the gas permeability properties of the blends developed by varying the mass fraction of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) using synthia.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly (biphenyl dimethyl carbonate) as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar volume: It is the volume occupied by one mole of a substance. Figure 1 shows that the molar volume of the composite decreases with increase in mass fraction of vinyl alcohol.

Density: Increase in density indicates decrease in porosity. A higher porosity will enhance the surface area making in suitable for absorption/adsorption applications. Figure 2 shows that the density of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Permeability of gas: Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium.Lower permeability indicates longer time lag for the gas to pass through the mebrane. Figure 3 shows that the permeability of oxygenthrough the composite decreases suddenly with increase in mass fraction of vinyl alcohol. Thus the results indicated that an increase in vinyl alcohol fraction reduces the permeability of different gases. The rate of permeability might be influence by the molecular weight of the gases.

CONCLUSION

The possibility of use of polyvinyl alcohol and andpoly(biphenyl dimethyl carbonate) to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties.The molar volume decreased and density increased with increase in vinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased tremendously with increase in mass fraction of vinyl alcohol. This indicates that these blends with high polyvinyl mass fraction can be used as good packaging materials. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is created bythe combination of two or more components. The compatibility of polyvinyl alcohol andpoly ethylene Terephthalate was study to form a miscible blend using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in polyvinyl alcohol fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide.The results showed that the permeability for all the gases decreases with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Synthia; In silico; Polyvinyl alcohol; Polyethylene terephthalate; Gas permeability

INTRODUCTION

Blends or composites to be formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to mix dissimilar components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilize the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of improvement of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material customized polymers paved the way to multi useful materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire evidence materials [3]. There are reports of inorganic additives in polypropylene; that can

enhance flame retardancy lacking increasing the weight [4]. Researchers have emphasize on synthesis and production of lightweight composite material having high strength important for enhancing fuel efficiency in the field of transport [5]. There are application of composites in structural Engineering due to high strength to weight ratio and resistance to decay. Thus, glass fiber durable polymers, latex polymer cementitious composites [6] were developed for building of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mention example relied on laboratory experiments. Usually blends are prepared by test and fault method andthis method is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico move toward to develop new blends. Software (Materials Studio [7]) has been used to identify well-matched pairs. Among the a mixture of polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, simple film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is extensively used in covering industry to form strong polymeric films. It is because of their high mechanical power, environmental stability and easy processability [10]. On the other hand, PVA is poisonous, semicrystalline, hydrophilic, biocompatible and simply soluble in water [11].

The consumption of plastics in Western Europe is of 38 million tonnes per year, the majority of which are used in the production of plastic packaging, household and domestic products, electrical and electronic goods [12]. There is also significant consumption of plastics for the structure and construction industry and automotive industry. The two main types of plastics are thermoplastics, which soften when heated and harden again when cooled, and thermosets, which harden by curing and cannot be re-moulded. About 80 % of plastics used in Western Europe are thermoplastics [13].For many waste landfills is the largest route for disposal throughout the countries of Europe. For some countries, including Lithuania, more than 60 % of municipal solid waste is disposed of to landfill [14]. Plastics make up high proportion of waste that volume and range used increases dramatically. Although plastics make up between 5 wt.% and 15 wt.% of municipal solid waste it comprises 20 % – 30 % of the volume [13]. Most plastics are non-degradable and take a long time to decompose, possibly up to hundreds of years – although no-one knows for certain as plastics have not existed for long enough, when they are landfilled. It is estimated that only about 50 % of the plastics produced in Western Europe each year are available for collection and recycling [12 – 14]. According to the experts from Kaunas University of Technology in Lithuania plastics reach about 82 thousands tones of municipal solid waste in 2004. It comprised about 24 kg for one inhabitant [15]. Waste recycling in Lithuania increases constantly andduring 2000–2006 it ranges between 20 – 35 thousand tonnes per year [16]. According to the Environmental Protection Agency (EPA) "recycling" is considered to be processing of waste to make new article. There are divided three distinct approaches to the recycling of post-consumer plastic materials :1) it could be reused directly; 2) undergo physical reprocessing, for example, grinding, melting and reforming; 3) be subjected to chemical treatment, when components are isolated and reprocessed for use in manufacture. A new widespread nomenclature of recycling was adopted by EPA. Primary recycling involves the use of pre-consumer industrial scrap and salvage, while physical reprocessing refers as secondary recycling and chemical processing as tertiary recycle [16].

MATERIALS AND METHODS

Software Used: Equipment studio part of Biovia software (Dassault Systemes of France) was used for analysis. The software utilize machine study techniques and normal algorithms to predict the level of interaction.

Methodology: The structure of polyvinyl alcohol andpoly ethylene Terephthalatewere fed to the synthia menu of equipment Studio. It was then run for different weight fractions of the mechanism. Different property of the composite was displayed in a tabular form. The values to be used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the gass properties of the composite.

RESULTS AND DISCUSSION

The use of polyvinyl alcohol andpoly ethylene Terephthalate as potential mechanism of a composite was analyze using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-define correlation (advanced quantitative structure-property relationships) to estimate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. accordingly, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic relations that give rise to it. However, the main shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculate.To overcome this limitation, the technique implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from diagram theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: The molar volume occupied by one mole of a substance at given at a given temperature and pressure.Figure 1 shows that the molar size of the composite decrease linearly with rise in dimension small part of mass fraction of polyvinyal alcohol.

Density: The density in increase indicates drop in porosity. A advance porosity will enhance the float up part creation in apposite for absorption application. Figure 2 shows that the density of the composite decrease linearly with incrase in mass fraction of polyvinayl alcohol.

Permeability of Gas: Permeability is the rate by which the gas can pass through the polymer membrane following the gas has come to equilibrium. Lower permeability indicate longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass division of polyvinyl alcohol.

Figure 4 shows that the permeability of nitrogen through the composite decrease with increase in mass fraction of polyvinyl alcohol. Figure-5 shows that the permeability of carbon dioxide through composite decrease with increases of mass fraction poly acrylic acid. As a consequence the domino effect indicated that an multiply in polyvinayl alcohol reduces the permeability capacity be weight by the molecular import of the gases.

CONCLUSION

Possibility of use poly acrylic acid and poly oxyethylene to form a homogeneous blend was explore using Biovia equipment Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in poly acrylic acid. The permeability property of the composite was studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are recognized experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving equipment, currency and time.

ABSTRACT

A blend is a combination of additional than one components. The preferred property of a blend is its homogeneity. The composition of poly acrylic acid and poly oxyethylene to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the composite to be studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The consequences indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol.This study will help determine pairs without performing laboratory experiments saving materials, currency and time

Keywords: Synthia; In silico;Polyacrylic Acid;Polyoxyethylene, Mechanical Properties

INTRODUCTION

Blends or composite are resources containing more than one part. The components do retain their identity in the combination. As it is very difficult to find multiple properties in a single material, it is advisableto combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilize the advantages of different materials; mix them to get the preferred property. Thus a blend saves time to develop a new material thereby dipping the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized

on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money.Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Acrylic acid have a board varity of application in dentistry as denture bases, artificial teeth , denture repair material, maxillofacial appliances for skeletal defects etc.[8] , bone repair [9] dispersing agent, superabsorbent polymer ion replace resin,etc. [10] Polyacrylic acid is a polyelectrolyte soluble in aqueous media at impartial pH It is used for prepare hydrogels. It is not poisonous and does not reason irritation [11].

The area of high pressure molecular credence polymers deliberate were poly (oxythylene) homopolymers (polyox) with molecular with molecular credence ranging from 4,000,000 to 7,000,000 power characteristics optional fine flowability for these resources and predicted case fulfil importance uniformity irritation[12]. Experiments showed a precise extreme notch of bulge for these resources in equality gastric and shock absorber solution[13]. These polymers bottle sustain the discharge percentage of mutually water-soluble and indecipherable drugs from drug providing system. The soothing molecular burden polymers control a fewer marked sustained-release provoke compare to the eminent molecular authority polymer data (i.e individual with 7,000,000 molecular weight). Intensification in the freedom percentage of the drug. The solubility of the drugs openly influenced the make available rate. Discharge kinetics were evaluated and appeared to be influenced by the molecular import of the polymer, the solubility of medicine, and the ratio of the drug to the polymer in the capsule[14]. Biomodal issue kinetics was exhibit by a amount of furosemide formulation (i.e. F5and F8).

MATERIALS AND METHODS

Software Used: Equipment studio module of Biovia software (Dassaults system of france) was old for analysis. The software utilizes piece of equipment education techniques and usual algorithems to predict the degree of interaction.

Methodology: Polyacrylic acid and oxyethelene were prepared by the synthia menu resources studio. It was subsequently enclose for characteristic weight fraction of the components. Varied properties of the composite were displayed in a tabular form. The ethics were second-hand to plot graphs to make out the impression of result little bit of poly-acryalic acid on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly acrylic acid and poly oxyethylenes as potential components of a composite was analyzed using Biovia equipment Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to calculate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group involvement cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of

group contributions is required and properties may be predicted for any polymer composed of any mixture of the subsequent The mechanical properties of the composite were premeditated based on size module, Bulk modules, Youngs modulus, Poission ratio and brittle stress fracture.

Bulk Modulus: The Bulk modulus of a substance is a measure of how resistance to compression that substance is. It is defined as the ratio of the infinitesimal pressure increase to the resulting relative to decrease of the volume. Figure 1 shows that the form modulus of the composite increase linearly with fuel in main part of acrylic acid.

Shear Modulus: The shear modulus is defined as the ratio of shear stress to shear strain. It is also known as modulus of rigidity. Figure 2 says that the modulus of rigidity of the composite increase with increase in mass fraction of poly acrylic acid.

Youngs Modulus: Young modulus, is a mechanical property that measures the stiffness of a solid material Figure 3 shows that the Youngs modulus of the composite increase with increase in mass fraction of poly acrylic acid.

Poisson Ratio: Poissons ratio is the ratio of transverse contraction strain to longitudinal extension strain in the direction of stretching force. Figure 4 shows that the poisson ratio of the composite decrease linearly with increase in mass fraction of acrylic acid.

Brittle Fracture Stress: A brittle fracture is the fracture of a metallic object or other material with appreciable prior plastic deformation. It is a break in a brittle piece of metal that failed because stress exceeded cohesion. Figure 5 shows that the brittle fracture stress of the composite decrease in increase in mass fraction of poly acrylic acid.

CONCLUSION

Possibility of use of the poly acrylic acid and poly oxyethylene to form a homogeneous blend was explored using BioviaMaterial Studio. The composition of the blend tobe analyzed with respect to mechanical properties. The mechanical properties of the composite to be studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of two properties decrease with increase mass fractionand the other properties increased with increase in mass fraction of poly acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, currency and time.

ABSTRACT

A blend is formed from the combination of two or more components. The change in properties of polyvinyl alcohol and poly-1, 2-α-D-galactosewas noticed to form a miscible blend using Biovia Materials Studio. The composition of polyvinyl alcohol and poly-1, 2-α-D-galactoseto provides desired mechanical properties of the blend were explored using Biovia Materials Studio. The mechanical properties of the blend were studied with considering the bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. From the results, it was noticed that the values of bulk modulus, shear modulus, Young' modulus decreased with increase in mass fraction of vinyl alcohol how ever the values of Poisson ratio and brittle stress fracture modulus increased with increase in mass fraction of vinyl alcohol. This study will help to determine pairs without doing laboratory experiments so that there is no use of materials and it is low cost.

INTRODUCTION

Blends or composites are formed from mixing of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber

composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. With considering various polymers, polyvinyl alcohol (PVA) is a encouraging material due to its high dielectric strength, easy film formation, adhesiveness and these properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy process ability [10]. On the other hand, PVA is non-toxic, semi-crystalline, biocompatible, hydrophilic and easily soluble in water [11]. There are different applications of glycol polymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery which is reported in earlier literatures[12]. It has been found that biopolymer blends possess good thermal stability [13]. This study is intended to study of mechanical properties of blend of polyvinyl alcohol and poly-1, 2-α-D-galactose.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly-1, 2-α-D-galactose werefed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1, 2-α-D-galactoseas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1, 2-α-D-galactose to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of Poisson ratio and brittle stress fracture increased with increase in mass fraction of vinyl alcohol. However, the values of bulk modulus, shear modulus and Young' modulus decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments so that there is no use of chemicals.

ABSTRACT

Polymer blend, combination of two or more component, has become the commercial importance due to its different properties of synergistic mixture. The study of physical and mechanical properties of the blend gives the opportunity for solving of different research problems. The mechanical properties of the blend using polyacrylic acid and poly-1, 2-α-D-galactose wereanalyzed using Biovia Materials Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of Poisson ratio and brittle stress fracture increased with increase in mass fraction of acrylic acid where as the values of bulk modulus, shear modulus and Young' modulus decreased with increase in mass fraction of acrylic acid. Since this technique does not require any chemical and money therefore it is very useful.

Keywords: Blend; Biovia Material Studio; Mechanical properties; Polyacrylic acid; In silico analysis

INTRODUCTION

Polymer blend, containing two or more component, has become the commercial importance due to its different properties of synergistic mixture and these properties are not associated with sum of properties of components. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

In earlier literature, nanomaterial decorated polymer composites have been designed for various applications such as dye removal, sensing, catalyst and packaging [1] and also carbon based nanomaterial assisted with polymers have been used in different environmental applications. Scientist has also synthesized natural fiber based polymer composites to enhance mechanical properties and water resistance [2]. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy

without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Acrylic acid is an organic compound which contains a vinyl group attached to carboxylic acid.It can be used in various purposes such as dispersing agent,artificial teeth and bone repair because of its biocompatibility, biodegradability nature and low toxicity [8-10]. Polyacrylic acid as water soluble polymer have been given as special attention because it can be applied in various applications such as ion exchange, efficient corrosion inhibitor and capacitorsand also it is used for preparing hydrogels [11]. It is not toxic and does not cause irritation. Researchers have used D-galactose in combination with other materials to different applications [12]. Poly-1, 2-α-D-galactose has been reported to be used in Curtius reaction. This study is intended to find out the change of gas permeability value of blend of polyacrylic acid and poly-1, 2-α-D-galactose with different proportions.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyacrylic acid and poly-1, 2-α-D-galactose were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acidon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acidand poly-1, 2-α-D-galactose as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite decreases linearly with increase in mass fraction of acrylic acid.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite decreases linearly with increase in mass fraction of acrylic acid.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite decreases linearly with increase in mass fraction of acrylic acid.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases with increase in mass fraction of acrylic acid.

CONCLUSION

The study of physical and mechanical properties of the blend gives the opportunity for solving of different research problems. The mechanical properties of polyacrylic acid and poly-1, 2-α-D-galactose was studied using Biovia Materials Studio for further use in various applications. The composition of the blend was analyzed with respect to mechanical properties. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of Poisson ratio and brittle stress fracture increased with increase in mass fraction of acrylic acid where as the values of bulk modulus, shear modulus and Young' modulus decreased with increase in mass fraction of acrylic acid.Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments

ABSTRACT

Hybrid polymeric materials with improved mechanical properties are in huge demand in connection to the industrial background. Blending is the simple technique to mixing different polymers and therefore, generating advanced functional materials. The composition of poly (biphenyl dimethylcarbonate) (PC) and polyether sulfone to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the composite were studied in terms of bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties decreased with increase in mass fraction of biphenyl dimethyl carbonate.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Polymer blend, Mechanical properties, Biovia, In-silico analysis, Compatibility

INTRODUCTION

Polymeric blends are usually offered improved physical and chemical properties like thermal, mechanical, gas barrier and biodegradability [1]. These properties are the prime interest for the researchers to design best packaging material. Gas permeability is sometimes offered as essential criterion to design the polymer for biomedical and industrial utilization. For instance, polymers with high barrier properties, i.e. low permeability, are mandatory for food packaging applications to prevent loss of aroma, color and food-value and to slow down spoilage [2]. Apart from this food packaging application; there are lots of other applications which require the polymers to have high, low or tailored permeability like, filters and membranes for gas or liquid separation [3], protective coatings (e.g., paints and varnishes) [4], polymer coatings for controlled drug release [5] and water desalination [6].The permeability of liquids and gases through polymer membranes (plastic films) may be happened by either a temperature or pressure gradient, or by concentration gradient or external force field. The ''solution-diffusion'' mechanism is generally used to depict the pathway of gas permeation. It involvesthree steps. In the first step

absorption of small molecules is happened into the membrane at the side of higher gradient (concentration, pressure, etc). On the other hand, second step involves the molecular diffusion through the membrane and the final step is related to desorption of those molecules from the membrane at the opposite side of lower gradient. The gas permeability in a polymer is generally varied with the nature of polymer and permeates. It may be accounted due to various degree of crystallinity and porosity of the polymers along with surface functionality (hydrophilic/ hydrophobic groups).The main aim of combining polymeric materials is to achieve the desired quality of the material. Among various polymers, polybiphenyldimethylcarbonate (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical strength[7]. As a resultof these excellent properties, PC has been largely employed in electronic and electronic appliances along with automotive industry, having an annual production of 6 million tons. Recent report by Behboudi *et.al.* [8] shows thatPC is blended withpolyvinyl chloride (PVC)to preparethe ultrafiltration membrane for water purification. On the other hand, PC is also blended with poly(vinylidene fluoride) (PVDF) to prepare mechanically strong multicomponent nanocomposites with nanostructural reinforcement of graphenenanoplates, carbon nanotube, and organically modified montmorillonite [9]. In another recent report Wen et al. reinforced the graphene plates into blend of polybutyleneterethalate and polycarbonate [10] to obtain electrical and thermal conductive materials. The unique material, formed from the blend of PC with polystyrene is also reported to sense organic vapours with incorporation of multiwalled carbon nanotubes (MWCNTs) [11]. Polycarbonate blended polysulfone material is recently observed to have improved thermal and mechanical properties[12].

Therefore, investigation of blending compatibility of polycarbonate with other polymer is the urgent need of current research to develop advanced functional materials. All the above mentioned examples relied on laboratory experiments. Usually, preparation of homogeneous blend in wet-lab condition, requires huge time and wastage of materials which can be minimized by in-silico approach through material studio [13] of "Biovia" software.. In present context, we are focusing to optimize the homogeneous blend composition of polybiphrnyldimethylcarbonate (PC) with polyether sulfone (PES) in terms of gas permeability. Among various engineering polymers, polyether sulfone (PES) is a high-temperature sustaining thermoplastic polymer with striking strength and chemical stability from various organic solvents. It belongs to the polysulfone family and contains an aryl-SO_2 subunit in their long chain structures. Nonetheless, the inherent hydrophobic property of PES makes this material sensitive to membrane fouling, restricting its more extensive applications in membrane based water treatment. Due to high chemical stability it is also preferably used for gas separation in harsh environment.

To improve the gas separation efficiency of PES, a few investigations have been performed. In a report, Adib et al. [14] incorporated the nanostructural silica to improve the gas separation. However, blending of PES with other hydrophilic polymer is one of the easiest routes to improve the efficiency of the gas separation. In another report, Mannan et al. [15] investigated the gas-permeation behavior of glassy poly(vinyl acetate) (PVAc)–PES hybrid films and PSF–PES film. Interestingly, it is found that the gas permeation properties of hybrid PSF–PES film is remain unaltered as compared to the properties of polyether sulfone. However on account of the PES–PVAc hybrid polymer, low selectivity was observed for gas separation and may be accounted as the phase separation in their blend. Kamal et al. [16] revealed that the blend with elastomers (like polydimethylsiloxane) leads to the improved gas permeation properties of the polydimethylsiloxane–PES hybrid. Akbarian et al.[17] prepared the PES based blend membranes for CO_2 gas separation with inclusion polyethylene glycol (PEG) as second polymer. Therefore, the present in-silico approach of blend analysis between poly(biphenyl dimethyl carbonate) (PC) and polyether sulfone (PES) may be utilized to optimize the composition to fabricate desirable functional materials with some improved physical and chemical properties.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polybiphenyldimethylcarbonate (PC) and polyether sulfone were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polybiphenyldimethylcarbonate (PC) on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polybiphenyldimethylcarbonate (PC) and polyether sulfoneas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the relative change in volume with anunit compressive or tensile stress acting uniformly over its surface. Figure 1 shows that the bulk modulus of the composite decreases linearly with increase in mass fraction of biphenyl dimethyl carbonate.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shearmoduli of the composite decreases linearly with increase in mass fraction of biphenyl dimethyl carbonate.

Young's modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young'smodulus of the composite decreases s linearly with increase in mass fraction of biphenyl dimethyl carbonates.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite decreases linearly with increase in mass fraction of biphenyl dimethyl carbonates.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite decreases linearly with increase in mass fraction of biphenyl dimethyl carbonate.

CONCLUSION

The possibility of use of poly (biphenyl dimethylcarbonate) (PC) and polyether sulfone to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties decreased with increase in mass fraction of biphenyl dimethyl carbonate. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and Polybenzamide to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Mechanical Properties, Silico, polyvinyl alcohol, polybenzamide.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance

flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].The strategy used here for synthesis of poly (benzamide)s relies on polymer end groups being more reactive than the monomer itself resulting in a kinetically controlled living chain-growth polymerization. Because of good control over the polydispersity and the molecular weight, a number of different polymer [12].I Specially synthesized rigid polybenzamide Nano whiskers of approximately 2000 nm length and 200 nm diameter were reported to increase tensile strength and Young's modulus without sacrificing high strainto-failure. [13]. This study is intended to identify the interaction of polyvinyl alcohol and Polybenzamide to form different composite.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and Polybenzamide were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight production of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and Polybenzamide as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of

group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass production of vinyl alcohol.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and Polybenzamide to form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of polyvinyl alcohol and 12bD galact to provide desired mechanical properties of the blend was explored using Biovia Materials Studio. The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol.This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: in silico, polyvinyl alcohol, poly-1,2-β-D galactose.

INTRODUCTION

Blends or composites are formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of

lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method and this technique is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11]. Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12]. It has been found that biopolymer blends possess good thermal stability [13].This study is intended to identify the interaction of polyvinyl alcohol and poly-1,2-β-D galactoseto form blend

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly-1,2-β-D galactosewere fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1,2-β-D galactoseas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Bulk Modulus: Bulk modulus is the measure of the decrease in volume with an increase in pressure. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Shear Modulus: It is defined as the ratio of shear stress and shear strain. It shows the response of the composite to shear deformation. Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Young's Modulus: It is defined as the ratio of stress and strain. It compares the relative stiffness of the composite. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Poisson Ratio: It is the ratio of lateral strain to longitudinal strain. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Brittle Fracture Stress: Brittle Fracture is the sudden, rapid cracking of a material under stress where the material exhibited practically no evidence of ductility or plastic degradation before the fracture occurs. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly-1,2-β-D galactoseto form a homogeneous blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties.The mechanical properties of the composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a combination of more than one components. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of polyvinyl alcohol. This study will help verify pairs without performing laboratory experiments saving equipment, currency and time.

Keywords: Synthia; Insilico; Polyacrylic acid; Polyoxyethylene, thermal and dielectric properties

INTRODUCTION

Blends or composite are resources containing more than one part. The components do retain their identity in the combination. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the preferred property. Thus a blend saves time to develop a new material thereby dipping the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high

strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) has been used to identify compatible pairs. Acrylic acid have a board varity of application in dentistry as denture bases, artificial teeth , denture repair material, maxillofacial appliances for skeletal defects etc.[8] , bone repair [9] dispersing agent, superabsorbent polymer ion replace resin,etc. [10] Polyacrylic acid is a polyelectrolyte soluble in aqueous media at impartial pH It is used for prepare hydrogels. It is not poisonous and does not reason irritation [11]. The area of high pressure molecular credence polymers deliberate were poly (oxythylene) homopolymers (polyox) with molecular with molecular credence ranging from 4,000,000 to 7,000,000 power characteristics optional fine flow ability for these resources and predicted case fulfil importance uniformity irritation[12].

Experiments showed a precise extreme notch of bulge for these resources in equality gastric and shock absorber solution[13]. These polymers bottle sustain the discharge percentage of mutually water-soluble and indecipherable drugs from drug providing system. The soothing molecular burden polymers control a fewer marked sustained-release provoke compare to the eminent molecular authority polymer data (i.e individual with 7,000,000 molecular weight).Intensification in the freedom percentage of the drug. The solubility of the drugs openly influenced the make available rate. Discharge kinetics were evaluated and appeared to be influenced by the molecular import of the polymer, the solubility of medicine, and the ratio of the drug to the polymer in the capsule [14]. Biomodal issue kinetics was exhibit by a amount of furosemide formulation (i.e. F5and F8).

MATERIALS AND METHODS

Software Used: Equipment studio module of Biovia software (Dassaults system of France) was old for study. The software utilize piece of equipment education techniques and usual algorithms to calculate the degree of communication.

Methodology: Polyacrylic acid and oxyethelene were prepared by the synthia menu resources studio. It was subsequently enclose for characteristic weight fraction of the components. Varied properties of the composite were displayed in a tabular form. The ethics were second-hand to plot graphs to make out the impression of result little bit of poly-acryalic acid on the themal properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly acrylic acid and poly oxyethylenes as potential components of a composite was analyzed using Biovia equipment Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to calculate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group involvement cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of

group contributions is required and properties may be predicted for any polymer composed of any mixture of the subsequent the thermal properties of the composite were premeditated based on Cp of the solid, thermal conductivity, dielectric constant.

Heat Capacity: Heat capacity is defined as the amount of heat to be supplied to a given mass of a material to produce a unit change in its temperature**.** Figure 1 shows that increase in heat capacity of the composite with increase in mass fraction of acrylic acid.

Thermal Conductivity: Thermal conductivity refers to the intrinsic ability of a material to transfer or conduct heat. Figure 2 shows that the thermal conductivity of the composite decrease with increase in mass fraction of poly acrylic acid.

Dielectric Constant: The dielectric constant is the ratio of the permittivity of a substance to the permittivity of free space .it is dimensionless value and is also called relative permittivity. Figure 3 shows that the dielectric constant of the composite increase with increase in mass fraction of acrylic acid.

CONCLUSION

The opportunity of exhaust of Polyacrylic acid and oxyethelene to type bring together was explored by Biovia Material Studio. The arrangement of the merger was analyzed with regard to heat capacity, thermal conductivity, dielectric constant. The results indicated that all the three parameters and one parameter is decrease in increase with increase in mass fraction of poly acrylic acid other two parameter increase with increase in mass fraction of acrylic acid. As a rule apparatus for a m? are identified experimentally. This in sillico examine will stop find out working of a merge without performing arts laboratory experiments materials, funds and time.

ABSTRACT

A blend is a combination of more than one components. The desired property of a blend is its homogeneity. The composition poly acrylic acid and poly oxythylene to provide desired mechanical property of the blend was explore using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability property. The molar volume and density decreased with increase in poly acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decrease with increase in mass fraction of polyvinyl alcohol. This learning will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Synthia; Insilico; Polyacrylic acid; Polyoxyethylene,gas permeability

INTRODUCTION

Blends or composite are resources containing more than one part. The components do retain their identity in the combination. As it is very difficult to find multiple properties in a single material, it is advisable to combine different components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the preferred property. Thus a blend saves time to develop a new material thereby dipping the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn significant attention in recent years. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance.

Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers; latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs. Acrylic acid have a board Varity of application in dentistry as denture bases, artificial teeth , denture repair material, maxillofacial appliances for skeletal defects etc.[8] , bone repair [9] dispersing agent, superabsorbent polymer ion replace resin, etc. [10] Polyacrylic acid is a polyelectrolyte soluble in aqueous media at impartial pH It is used for prepare hydrogels. It is not poisonous and does not reason irritation [11]. The area of high pressure molecular credence polymers deliberate were poly (oxythylene) homopolymers (polyox) with molecular with molecular credence ranging from 4,000,000 to 7,000,000 power characteristics optional fine flow ability for these resources and predicted case fulfil importance uniformity irritation[12].

Experiments showed a precise extreme notch of bulge for these resources in equality gastric and shock absorber solution[13]. These polymers bottle sustain the discharge percentage of mutually water-soluble and indecipherable drugs from drug providing system. The soothing molecular burden polymers control a fewer marked sustained-release provoke compare to the eminent molecular authority polymer data (i.e individual with 7,000,000 molecular weight). Intensification in the freedom percentage of the drug. The solubility of the drugs openly influenced the make available rate. Discharge kinetics were evaluated and appeared to be influenced by the molecular import of the polymer, the solubility of medicine, and the ratio of the drug to the polymer in the capsule[14]. Biomodal issue kinetics was exhibit by a amount of furosemide formulation (i.e. F5and F8).

MATERIALS AND METHODS

Software Used: Equipment studio module of Biovia software (Dassaults system of France) was old for analysis. The software utilizes piece of equipment education techniques and usual algorithms to predict the degree of interaction.

Methodology: Polyacrylic acid and oxyethelene were prepared by the synthia menu resources studio. It was subsequently enclose for characteristic weight fraction of the components. Diverse properties of the composite were displayed in a tabular form. The ethics were second-hand to plot graphs to make out the impression of consequence little bit of poly-acryalic acid on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of poly acrylic acid and poly oxyethylenes as potential components of a composite was analyzed using Biovia equipment Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to calculate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer

contains a group for which the group involvement cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any mixture of the subsequent nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Molar Volume: The molar volume occupied by one mole of a substance at given at a given temperature and pressure. Figure 1 shows that the molar size of the composite decrease linearly with rise in dimension small part of mass fraction of acrylic acid.

Density: The density in increase indicates drop in porosity. An advance porosity will enhance the float up part creation in apposite for absorption application. Figure 2 shows that the density of the composite increase linearly with growth in bulk part of acrylic acid.

Permeability of Gas: Permeability is the rate by which the gas can pass through the polymer membrane following the gas has come to equilibrium. Lower permeability indicate longer time lag for the gas to pass through the membrane. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass division of acrylic acid.

Figure 4 shows that the permeability of nitrogen through the composite decrease with increase in mass fraction of acryalic acid. Figure-5 shows that the permeability of carbon dioxide through composite decrease with increases of mass fraction poly acrylic acid. As a consequence the domino effect indicated that an multiply in polyacryalic acid little bit reduces the permeability capacity be weight by the molecular import of the gases.

CONCLUSION

Possibility of use poly acrylic acid and poly oxyethylene to form a homogeneous blend was explore using Biovia equipment Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in poly acrylic acid. The permeability property of the composite was studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeabilityfor all the gases decreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are recognized experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving equipment, currency and time.

INTRODUCTION

Blends or composites to be formed with combination of more than one component where components do retain their identity in the mixture. As it is very difficult to find multiple properties in a single material, it is advisable to mix dissimilar components thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of improvement of products with desired properties. Polymer blends can be made of two or more polymers, or fibers and polymer, or particles and polymer.

Nano material customized polymers paved the way to multi useful materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire evidence materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy lacking increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite material having high strength important for enhancing fuel efficiency in the field of transport [5]. There is application of composites in structural Engineering due to high strength to weight ratio

and resistance to decay. Thus, glass fiber durable polymers; latex polymer cementitious composites [6] were developed for building of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mention example relied on laboratory experiments. Usually blends are prepared by test and fault method andthis method is a low cost and less time consuming method. Thus, researchers have focused on the use of in silico move toward to develop new blends. Software (Materials Studio [7]) has been used to identify well-matched pairs. Among the a mixture of polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, simple film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is extensively used in covering industry to form strong polymeric films. It is because of their high mechanical power, environmental stability and easy processability [10]. On the other hand, PVA is poisonous, semicrystalline, hydrophilic, biocompatible and simply soluble in water [11].

The consumption of plastics in Western Europe is of 38 million tonnes per year, the majority of which are used in the production of plastic packaging, household and domestic products, electrical and electronic goods [12]. There is also significant consumption of plastics for the structure and construction industry and automotive industry. The two main types of plastics are thermoplastics, which soften when heated and harden again when cooled, and thermosets, which harden by curing and cannot be re-moulded. About 80 % of plastics used in Western Europe are thermoplastics [13].For many waste landfills is the largest route for disposal throughout the countries of Europe. For some countries, including Lithuania, more than 60 % of municipal solid waste is disposed of to landfill [14]. Plastics make up high proportion of waste that volume and range used increases dramatically. Although plastics make up between 5 wt.% and 15 wt.% of municipal solid waste it comprises 20 % – 30 % of the volume [13]. Most plastics are non-degradable and take a long time to decompose, possibly up to hundreds of years – although no-one knows for certain as plastics have not existed for long enough, when they are landfilled.

It is estimated that only about 50 % of the plastics produced in Western Europe each year are available for collection and recycling [12 – 14]. According to the experts from Kaunas University of Technology in Lithuania plastics reach about 82 thousands tones of municipal solid waste in 2004. It comprised about 24 kg for one inhabitant [15]. Waste recycling in Lithuania increases constantly andduring 2000–2006 it ranges between 20 – 35 thousand tonnes per year [16]. According to the Environmental Protection Agency (EPA) "recycling" is considered to be processing of waste to make new article. There are divided three distinct approaches to the recycling of post-consumer plastic materials: 1) it could be reused directly; 2) undergo physical reprocessing, for example, grinding, melting and reforming; 3) be subjected to chemical treatment, when components are isolated and reprocessed for use in manufacture. A new widespread nomenclature of recycling was adopted by EPA. Primary recycling involves the use of pre-consumer industrial scrap and salvage, while physical reprocessing refers as secondary recycling and chemical processing as tertiary recycle [16].

MATERIALS AND METHODS

Software Used: Equipment studio part of Biovia software (Dassault Systemes of France) was used for analysis. The software utilize machine study techniques and normal algorithms to predict the level of interaction.

Methodology: The structure of polyvinyl alcohol andpoly ethylene Terephthalatewere fed to the synthia menu of equipment Studio. It was then run for different weight fractions of the mechanism. Different property of the composite was displayed in a tabular form. The values to be used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the thermal and dielectric properties of the composite.

RESULTS AND DISCUSSION

The use of polyvinyl alcohol andpoly ethylene Terephthalate as potential mechanism of a composite was analyze using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-define correlation (advanced quantitative structure-property relationships) to estimate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Accordingly, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic relations that give rise to it. However, the main shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculate.To overcome this limitation, the technique implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from diagram theory are employed. The thermal properties of the composite were premeditated based on Cp of the solid, thermal conductivity, dielectric constant.

Heat Capacity: Heat capacity is defined as the amount of heat to be supplied to a given mass of a material to produce a unit change in its temperature Figure 1 shows that decrease in heat capacity of the composite with increase in mass fraction of vinyl alcohol.

Thermal Conductivity: Thermal conductivity refers to the intrinsic ability of a material to transfer or conduct heat. Figure 2 shows that the thermal conductivity of the composite decrease with increase in mass fraction of vinyl alcohol.

Dielectric Constant: The dielectric constant is the ratio of the permittivity of a substance to the permittivity of free space .it is dimensionless value and is also called relative permittivity. Figure 3 shows that the dielectric constant of the composite increase with increase in mass fraction of vinyl alcohol.

CONCLUSION

The opportunity of exhaust poly vinyl alcohol polyethylene terephthalate to type a bring together was explored by Biovia resources studio. The arrangement of the merger was analyzed with regard to heat capacity, thermal conductivity, dielectric constant. The results indicated that all the three parameters and one parameter is decrease in increase with increase in mass fraction of poly acrylic acid other two parameter increase with increase in mass fraction of acrylic acid. As a rule apparatus for a m? are identified experimentally. This in sillico examine will stop find out working of a merge without performing arts laboratory experiments materials, funds and time.

ABSTRACT

Polymeric blend is a reasonable suggested method to obtain the new polymer materials having properties better to those of the individual constituents. Dielectric constant is an important parameter to judge a better dielectric material. Further, polymer blend with high thermal properties can be used in various packaging industry. In this paper, the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. From the results it was noticed that all those parameters increased with increase in mass fraction of poly biphenyldimethyl carbonate. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend; Biovia Material Studio; Dielectric constant; Thermal properties; Polybiphenyldimethyl carbonate; *In silico* analysis

INTRODUCTION

Recently, Researchers have given more attention towards fabrication of good dielectric materials and high thermal stable materials because of their many applications in industry. For better dielectric material it is very much important to find out the various important parameters such as such as high dielectric constant, low dielectric loss [1]. Further, thermal properties of the material are used to judge the high thermal stable material. Therefore polymer is becoming hot field of science and technology to act as a good dielectric and thermal stable material. But there are certain limitations for synthesis of new polymer such as synthesis technology, cost of production and source of raw material. Hence, blending polymers is a reasonable proposed technique to achieve the new polymer materials, having properties of the designed material better to those of the individual constituents. Polymer blends are generally simpler process and have fantastic flexibility. These have many applications in the field of electronic industry. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4].

Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementations composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

In present context, the dielectric and thermal properties of blend are analyzed containing polybiphrnyl dimethylcarbonate (PC) with polydimethylsiloxane (PDMS). It is a polymeric organosilicon compound, particularly known for its unusual rheological behaviors. Moreover it is optically clear, non-toxic and non-flammable. Polydimethyl siloxane (PDMS) shows wide applications like contact lenses, medical devices and preparing elastomer materials. It is also used in making of lubricants and heat-resistant tiles. Recently, the PDMS based blend membranes with polyvinyl chloride-co-vinyl acetate (PVCA)were synthesized for CO_2 seperation [17]. Polydimethyl siloxane is also used in biomedical application like maxillofacial prosthetics, artificial blood vessels and articular cartilage replacement, when it is blended with poly ether (ether) ketone (PEEK) [18]. The present in-silico approach of blend analysis between poly biphenyldimethyl carbonate (PC) and polydimethyl siloxane (PDMS) may be utilized to know the good dielectric and thermal properties at optimized ratio.Therefore, the dielectric constant and thermal properties of the blend is studied with different acrylic acid proportions.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polybiphenyldimethyl carbonate and Polydimethyl siloxane were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of poly biphenyldimethyl carbonate on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polybiphenyldimethyl carbonateand Polydimethyl siloxaneas potential components of a composite was analyzed using Biovia Materials Studio. Biovia Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite decreases linearly with increase in mass fraction of poly biphenyldimethyl carbonate.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of biphenyldimethyl carbonate.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of biphenyldimethyl carbonates.

CONCLUSION

Different properties the blend of polybiphenyldimethyl carbonate and Polydimethyl siloxane was analyzed using Biovia Materials Studio. Because of enhance of different properties such as dielectric constant and thermal it can be used in various applications. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parametersincreased with increase in mass fraction of acrylic acid so that his blend with high biphenyldimethyl carbonate proportions can be used in various applications Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments with low cost.

ABSTRACT

Blending polymers is a reasonable proposed technique to achieve the new polymer materials having properties better to those of the individual constituents. Dielectric constant is an important parameter to judge a better dielectric material. Further, polymer blend with high thermal properties can be used in various packaging industry. In this paper, the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. From the results it was noticed that all those parameters decreased with increase in mass fraction of acrylic acid so that the value of these parameters will increase with increase in mass fraction of α-D-galactose. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Blend; Biovia Material Studio; Dielectric constant; Thermal properties; Polyacrylic acid; In silico analysis

INTRODUCTION

Dielectric materials have drawn considerable attention because of their many applications in industry. For better dielectric material it is very much important to find out the various important parameters such as such as high dielectric constant, low dielectric loss [1]. Further, thermal properties of the material are considered for the use of materials in various applications such as packaging industry. Therefore polymer is becoming hot field of science and technology for scientist. But there are certain limitations for synthesis of new polymer such as synthesis technology, cost of production and source of raw material. Hence, blending polymers is a reasonable proposed technique to achieve the new polymer materials, having properties of the designed material better to those of the individual constituents. Polymer mixes are generally simpler process and and have fantastic flexibility. These have many applications in the field of electronic industry. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without

increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Acrylic acid is an organic compound which contains a vinyl group attached to carboxylic acid. It can be used in various purpose such as dispersing agent, artificial teeth and bone repair because of its biocompatibility, biodegradability nature and low toxicity [8-10]. Polyacrylic acid as water soluble polymer have been given as special attention because it can be applied in various applications such as ion exchange, efficient corrosion inhibitor and capacitorsand also it is used for preparing hydrogels. It is not toxic and does not cause irritation [11].

Researchers have used D-galactose in combination with other materials to different applications [12]. Poly-1, 2-α-D-galactose has been reported to be used in Curtius reaction.This study is intended to find out the change of gas permeability value of blend of polyacrylic acid and poly-1, 2-α-D-galactose with different proportions. In this paper, the change in thermal and dielectric properties of blend is analyzed with respect to the change in acrylic acid proportions theoretically. From thermal properties, it can be found the thermal stability of the blend. Further, the dielectric constant of the blend is studied with different acrylic acid proportions.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyacrylic acid and poly-1, 2-α-D-galactosewere fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyacrylic acidon the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyacrylic acidand poly-1, 2-α-D-galactoseas potential components of a composite was analyzed using Biovia Materials Studio. Biovia Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of

group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite decreases linearly with increase in mass fraction of acrylic acid.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite decreases linearly with increase in mass fraction of acrylic acid.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite decreases with increase in mass fraction of acrylic acid.

CONCLUSION

Different properties the blend of polyacrylic acidand poly-1, 2-α-D-galactosewas analyzed using Biovia Materials Studio. Because of enhance of different properties such as dielectric constant and thermal it can be used in various applications. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters decreased with increase in mass fraction of acrylic acid so that all the three parameters will increase with increase in mass fraction of α-D-galactose. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

In this paper, we have tried to explore the thermal and dielectric property of polyvinyl alcohol and poly (biphenyl dimethyl carbonate) to form a miscible blend using Biovia Materials Studio. Usually, blend is a mixture of two or more components and expected to have homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of vinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: In silico, thermal and dielectric properties, polyvinyl alcohol and poly(biphenyl dimethyl carbonate), Synthia, Biovia

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi-functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of

transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11].

Poly (biphenyl dimethyl carbonate) has an amorphous structure and is considered to be an engeeniering plastic. Its wide applications include impact resistance, strength, high temperature performance, toughness, load bearing capabilities, dimensional stability, flame retarding capabilities, and excellent optical clarity. Based on these properties they have commercialized as outdoor signs, eye glasses, compact disks, CD-ROM, aircraft windows, automotive windows and instrument panels, food trays and containers, automotive headlamp covers, housings of appliances, and medical devices [12, 13]. It has been found that biopolymer blends possess good thermal stability [14]. This study is intended to explore the thermal and dielectric properties of the blends developed by varying the mass fraction of polyvinyl alcohol and poly (biphenyl dimethyl carbonate) using synthia.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) as potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite decreases with increase in mass fraction of vinyl alcohol.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite decreases linearly with increase in mass fraction of vinyl alcohol.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases linearly with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and poly(biphenyl dimethyl carbonate) to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that heat capacity and thermal conductivitydecreased with increase in mass fraction of vinyl alcohol whereas the dielectric constant increases. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one components. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Thermal and dielectric properties, Silico, polyvinyl alcohol, polybenzamide

INTRODUCTION

Blends or composites are materials containing more than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials, mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials [3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were

developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11]. The strategy used here for synthesis of poly(benzamide)s relies on polymer end groups being more reactive than the monomer itself resulting in a kinetically controlled living chain-growth polymerization. Because of good control over the polydispersity and the molecular weight, a number of different polymer [12].Polybenzamide have been reported to be used in Curtius reaction. This study is intended to identify the interaction of polyvinyl alcohol and polybenzamide to form composite.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and polybenzamide were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and polybenzamideas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase. Figure 1 shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient. It refers to the intrinsic ability of a material to transfer heat. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of vinyl alcohol.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of vinyl alcohol.

CONCLUSION

The possibility of use of polyvinyl alcohol and polybenzamideto form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parametersincreased with increase in mass fraction of vinyl alcohol. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of polyvinyl alcohol. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Thermal and dielectric property, in silico, polyvinyl alcohol, poly-1,2-β-D galactose.

INTRODUCTION

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend utilizes the advantages of different materials; mix them to get the desired property. Thus a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties.Polymer blends can be made of two or more polymers, or fibres and polymer, or particles and polymer.

Nano material modified polymers paved the way to multi functional materials. Polymers coupled with carbon based (graphene, carbon nano-tube) nano-materials [1] have drawn attention. Biodegradable polymers- natural fiber composites [2] have been reported to enhance mechanical properties and water resistance. Researchers are working on fire retardant/fire proof materials[3]. There are reports of inorganic additives in polypropylene; that can enhance flame retardancy without increasing the weight [4]. Researchers have emphasized on synthesis and production of lightweight composite materials having high strength important for enhancing fuel efficiency in the field of transportation [5]. There are applications of composites in structural Engineering due to high strength to weight ratio and resistance to corrosion. Thus, glass fiber reinforced polymers, latex polymer cementitious composites [6] were

developed for construction of bridges, light rail transit, mining and tunneling, retaining walls and other waterside buildings. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach to develop new blends. Software (Materials Studio [7]) have been used to identify compatible pairs.

Among the various polymers, polyvinyl alcohol (PVA) is a promising material due to its high dielectric strength, easy film formation, adhesiveness and whose properties can be controlled by dopant concentrations [8, 9]. The film forming ability of PVA is widely used in packaging industry to form strong polymeric films. It is because of their high mechanical strength, environmental stability and easy processability [10]. On the other hand, PVA is non-toxic, semicrystalline, hydrophilic, biocompatible and easily soluble in water [11]. Researchers have found applications of glycopolymers (synthetic polymers containing pendant carbohydrate groups) in the separation and removal of toxins and bacteria, tumor cell recognition and glucose-responsive insulin delivery [12]. It has been found that biopolymer blends possess good thermal stability [13].This study is intended to identify the interaction of polyvinyl alcohol and poly-1,2-β-D galactoseto form blend.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systemes of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction.

Methodology: The structures of polyvinyl alcohol and poly-1,2-β-D galactose were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polyvinyl alcohol on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polyvinyl alcohol and poly-1,2-β-D galactoseas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated.

To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. ABSTRACT

Preparing blend with two or more polymeric components is the easiest trend in developing hybrid materials with improved thermal and electrical properties. Depending on the compatibility of the constituting components, it may undergo in well mixing or phase separation within the hybrid blend. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that only heat capacity of the hybrid material increases, while other properties like thermal conductivity and dielectric constant are decreased with increase of mass fraction of biphenyldimethyl carbonate. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

Keywords: Hybrid Polymer, Thermal properties, Dielectric properties, Biovia,In-silico analysis

INTRODUCTION

The current age is essentially managing the improvement of existing one in all areas of science and technology. Polymeric blends are usually offered improved physical and chemical properties like thermal, mechanical, gas barrier and biodegradability [1]. These properties are the prime interest for the researchers to design best packaging material. Gas permeability is sometimes offered as essential criterion to design the polymer for biomedical and industrial utilization. For instance, polymers with high barrier properties, i.e. low permeability, are mandatory for food packaging applications to prevent loss of aroma, color and food-value and to slow down spoilage [2]. Apart from this food packaging application; there are lots of other applications which require the polymers to have high, low or tailored permeability like, filters and membranes for gas or liquid separation [3], protective coatings (e.g., paints and varnishes) [4], polymer coatings for controlled drug release [5] and water desalination [6].The permeability of liquids and gases through polymer membranes (plastic films) may be happened by either a temperature or pressure gradient, or by concentration gradient or external force field. The ‘‘solution-diffusion’’ mechanism is generally used to depict the pathway of gas permeation. It involvesthree steps. In the first step

absorption of small molecules is happened into the membrane at the side of higher gradient (concentration, pressure, etc). On the other hand, second step involves the molecular diffusion through the membrane and the final step is related to desorption of those molecules from the membrane at the opposite side of lower gradient. The gas permeability in a polymer is generally varied with the nature of polymer and permeates. It may be accounted due to various degree of crystallinity and porosity of the polymers along with surface functionality (hydrophilic/ hydrophobic groups).The main aim of combining polymeric materials is to achieve the desired quality of the material. Among various polymers, polybiphenyldimethylcarbonate (PC) is a widely used engineering plastics because of its physical and chemical properties like ductility, good thermal stability, excellent transparency, and high mechanical strength[7]. As a resultof these excellent properties, PC has been largely employed in electronic and electronic appliances along with automotive industry, having an annual production of 6 million tons. Recent report by Behboudiet. al. [8] shows thatPC is blended withpolyvinyl chloride (PVC)to preparethe ultrafiltration membrane for water purification. On the other hand, PC is also blended with poly(vinylidene fluoride) (PVDF) to prepare mechanically strong multicomponent nanocomposites with nanostructural reinforcement of graphenenanoplates, carbon nanotube, and organically modified montmorillonite [9].

In another recent report Wen et al. reinforced the graphene plates into blend of polybutyleneterethalate and polycarbonate [10] to obtain electrical and thermal conductive materials. The unique material, formed from the blend of PC with polystyrene is also reported to sense organic vapours with incorporation of multiwalled carbon nanotubes (MWCNTs) [11]. Polycarbonate blended polysulfone material is recently observed to have improved thermal and mechanical properties[12]. Therefore,investigationof blending compatibility of polycarbonate with other polymer is the urgent need of current research to develop advanced functional materials. All the above mentioned examples relied on laboratory experiments. Usually, preparation of homogeneous blend in wet-lab condition, requires huge time and wastage of materials which can be minimized by in-silico approach through material studio [13] of "Biovia" software.. In present context, we are focusing to optimize the homogeneous blend composition of polybiphrnyldimethylcarbonate (PC) with polyether sulfone (PES) in terms of gas permeability. Among various engineering polymers, polyether sulfone (PES) is a high-temperature sustaining thermoplastic polymer with striking strength and chemical stability from various organic solvents. It belongs to the polysulfone family and contains an aryl-SO_2 subunit in their long chain structures. Nonetheless, the inherent hydrophobic property of PES makes this material sensitive to membrane fouling, restricting its more extensive applications in membrane based water treatment. Due to high chemical stability it is also preferably used for gas separation in harsh environment.

To improve the gas separation efficiency of PES, a few investigations have been performed. In a report, Adib et al. [14] incorporated the nanostructural silica to improve the gas separation. However, blending of PES with other hydrophilic polymer is one of the easiest routes to improve the efficiency of the gas separation. In another report, Mannan et al. [15] investigated the gas-permeation behavior of glassy poly(vinyl acetate) (PVAc)–PES hybrid films and PSF–PES film. Interestingly, it is found that the gas permeation properties of hybrid PSF–PES film is remain unaltered as compared to the properties of polyether sulfone. However on account of the PES–PVAc hybrid polymer, low selectivity was observed for gas separation and may be accounted as the phase separation in their blend. Kamal et al. [16] revealed that the blend with elastomers (like polydimethylsiloxane) leads to the improved gas permeation properties of the polydimethylsiloxane–PES hybrid. Akbarian et al.[17] prepared the PES based blend membranes for CO_2 gas separation with inclusion polyethylene glycol (PEG) as second polymer. Therefore, the present in-silico approach of blend analysis between poly(biphenyl dimethyl carbonate) (PC) and polyether sulfone (PES) may be utilized to optimize the composition to fabricate desirable functional materials with some improved physical and chemical properties.

MATERIALS AND METHODS

Software Used: Materials studio module of Biovia software (Dassault Systems of France) was used for analysis. The software utilizes machine learning techniques and standard algorithms to predict the level of interaction

Methodology: The structures of polybiphenyl dimethyl carbonate and polyether sulfone were fed to the synthia menu of Materials Studio. It was then run for different weight fractions of the components. Different properties of the composite were displayed in a tabular form. The values were used to plot graphs to identify the effect of weight fraction of polybiphenyl dimethyl carbonate on the mechanical properties of the composite.

RESULTS AND DISCUSSION

In this work the use of polybiphenyl dimethyl carbonateand polyether sulfoneas potential components of a composite was analyzed using Biovia Materials Studio. BIOVIA Materials Studio Synthia uses pre-defined correlations (advanced quantitative structure-property relationships) to evaluate a wide range of polymer properties. Group additive methods were used for many years to predict the properties of polymers as well as small molecules. These methods are extremely fast and easy to use. Consequently, they are of greatest utility when a rapid estimate of a property is required without a detailed understanding of the atomistic interactions that give rise to it. However, the principal shortcoming of these methods is their dependence upon a database of group contributions. Thus, if a polymer contains a group for which the group contribution cannot be estimated, then the property of that polymer cannot be calculated. To overcome this limitation, the method implemented in Synthia uses topological information about polymers in the predictive correlations. The connectivity indices derived from graph theory are employed. Thus, no database of group contributions is required and properties may be predicted for any polymer composed of any combination of the following nine elements: carbon, hydrogen, nitrogen, oxygen, silicon, sulfur, fluorine, chlorine, bromine.

Heat Capacity: It is the amount of heatrequired to raise the temperature of one unit weight of a substance by 1°C without change of phase.Figure 1 shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of biphenyl dimethyl carbonate.

Thermal Conductivity: It indicates the correlation between heat flux per unit area and temperature gradient.It refers to the intrinsic ability of a material to transfer heat.Figure 2 shows that the thermal conductivity of the composite decreases linearly with increase in mass fraction of biphenyl dimethyl carbonate.

Dielectric Constant: It is defined as the ratio of the electric permeability of the material to the electric permeability of free space. As the dielectric constant increases, the electric flux density increases, while all other factors are maintained constant.Figure 3 shows that the dielectric constants of the composite decreases with increase in mass fraction of biphenyl dimethyl carbonate.

CONCLUSION

The possibility of use of poly (biphenyl dimethyl carbonate) and polyether sulfone to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant.The results indicated that only heat capacity of the hybrid material increases, while other properties like thermal conductivity and dielectric constant are decreased with increase of mass fraction of biphenyl dimethyl carbonate. Usually components for a blend are identified experimentally. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code Clc1nc(Cl)nc(n1)N2CCCc3ccccc23.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology

"Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral

enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code Clc1nc(Cl)nc(n1)N2CCCc3ccccc23. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code Clc1nc(Cl)nc(n1)N2CCCc3ccccc23. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code C[C@H]1C[C@H](CC(C)(C)C1)OC=O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code C[C@H]1C[C@H](CC(C)(C)C1)OC=O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code C[C@@H]1CC(C)(C)N(CCO)c2cc(C)ccc12.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology

"Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used

CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code C[C@@H]1CC(C)(C)N(CCO)c2cc(C)ccc12. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code C[C@@H]1CC(C)(C)N(CCO)c2cc(C)ccc12.

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology

"Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral

enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code COC(=O)CS[C@H](C)CC(=O)OC. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code COC(=O)CS[C@H](C)CC(=O)OC.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code COC(=O)[C@H]1SCC(=O)[C@H]1C(=O)OC.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology

"Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral

enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code COC(=O)[C@H]1SCC(=O)[C@H]1C(=O)OC. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code COC(=O)[C@H]1SCC(=O)[C@H]1C(=O)OC.

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code NN1C=Cc2ccccc2C1=N. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code NN1C=Cc2ccccc2C1=N.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC1(C)SC(C)(C)N(C=O)[C@H]1C(=O)O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology

"Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used

CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC1(C)SC(C)(C)N(C=O)[C@H]1C(=O)O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC1(C)SC(C)(C)N(C=O)[C@H]1C(=O)O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code C[C@H](SCS[C@H](C)C(=O)O)C(=O)O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code C[C@H](SCS[C@H](C)C(=O)O)C(=O)O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code C[C@H](SCS[C@H](C)C(=O)O)C(=O)O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code Cc1ccc(cc1)S(=O)(=O)NC(=O)NN2CCCCCC2.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code Cc1ccc(cc1)S(=O)(=O)NC(=O)NN2CCCCCC2. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code Cc1ccc(cc1)S(=O)(=O)NC(=O)NN2CCCCCC2.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CCOC(=O)[C@@H]1C[NH2+]CCC1=O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CCOC(=O)[C@@H]1C[NH2+]CCC1=O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CCOC(=O)[C@@H]1C[NH2+]CCC1=O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code Oc1cc([O-])nc2ccccc12.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code Oc1cc([O-])nc2ccccc12. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code Oc1cc([O-])nc2ccccc12.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code OC(=O)C[NH2+]Cc1ccccc1.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code OC(=O)C[NH2+]Cc1ccccc1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code OC(=O)C[NH2+]Cc1ccccc1.

Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC(C)[C@@H]1CC[C@@H](C)C[C@H]1OC(=O)C(O)O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC(C)[C@@H]1CC[C@@H](C)C[C@H]1OC(=O)C(O)O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC(C)[C@@H]1CC[C@@H](C)C[C@H]1OC(=O)C(O)O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC[N+](CC)(CC)S(=O)(=O)[N-]C(=O)OC.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC[N+](CC)(CC)S(=O)(=O)[N-]C(=O)OC. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC[N+](CC)(CC)S(=O)(=O)[N-]C(=O)OC.

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC(=O)NC(NC(=O)C)C(=O)c1ccccc1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC(=O)NC(NC(=O)C)C(=O)c1ccccc1.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code OC(=O)CCC(=O)N(Nc1ccccc1)c2ccccc2.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code OC(=O)CCC(=O)N(Nc1ccccc1)c2ccccc2. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code OC(=O)CCC(=O)N(Nc1ccccc1)c2ccccc2.

Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CCNC(=S)SCCC(=O)O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CCNC(=S)SCCC(=O)O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CCNC(=S)SCCC(=O)O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC(C)COC(=O)OCC(C)C.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC(C)COC(=O)OCC(C)C. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC(C)COC(=O)OCC(C)C.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code OC(=O)CCCc1ccc(cc1)C(=O)c2ccccc2C(=O)O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code OC(=O)CCCc1ccc(cc1)C(=O)c2ccccc2C(=O)O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code OC(=O)CCCc1ccc(cc1)C(=O)c2ccccc2C(=O)O.

Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC(=O)NC1=NC(=O)NC=C1.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC(=O)NC1=NC(=O)NC=C1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC(=O)NC1=NC(=O)NC=C1.

Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC(C)C1=CC(=O)Oc2c3CCCN4CCCc(cc12)c34.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC(C)C1=CC(=O)Oc2c3CCCN4CCCc(cc12)c34. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC(C)C1=CC(=O)Oc2c3CCCN4CCCc(cc12)c34.

Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code OC[C@@H](O)COc1ccc(Cc2ccc(OC[C@H](O)CO)cc2)cc1.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code OC[C@@H](O)COc1ccc(Cc2ccc(OC[C@H](O)CO)cc2)cc1. Positive values of "-CDOCK Energy and - CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code OC[C@@H](O)COc1ccc(Cc2ccc(OC[C@H](O)CO)cc2)cc1.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CC1=CC(=O)Oc2cc(OC(=O)c3ccc(NC(=N)N)cc3)ccc12. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CC1=CC(=O)Oc2cc(OC(=O)c3ccc(NC(=N)N)cc3)ccc12.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC(C)[C@H]1CC[C@H](C)C[C@@H]1OCC(=O)O.

Keywords: Corona, Virus, Docking, Pharmacophore

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code COc1ccc2C(=CC(=O)Oc2c1)CC(=O)ON3C(=O)CCC3=O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code COc1ccc2C(=CC(=O)Oc2c1)CC(=O)ON3C(=O)CCC3=O.

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code Oc1ccc(O)c(Cc2nc3ccccc3s2)c1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials.

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code Oc1ccc(O)c(Cc2nc3ccccc3s2)c1.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC[C@H](C)NC(=O)c1ccccc1C.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CN1C(=O)N(C)c2ncn(Cc3ncc[nH]3)c2C1=O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CN1C(=O)N(C)c2ncn(Cc3ncc[nH]3)c2C1=O.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code COC(=O)CCC1=NO[C@H](C[C@@H]2CC(=NO2)CCC(=O)OC)C1.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized.

Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3].The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code CN(C)Cc1c(C)[nH]c(C)c1CN(C)C. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code CN(C)Cc1c(C)[nH]c(C)c1CN(C)C.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CNC(=O)CN1C(=O)CCC1=O.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code Cc1ccc2[C@H](CO)c3ccccc3[C@H](CO)c2c1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code Cc1ccc2[C@H](CO)c3ccccc3[C@H](CO)c2c1.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code OC(=O)\C=C\C1=CC(=O)C(=CO1)OCc2ccccc2.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code COc1ccc(\C(=N\O)\c2ccc(N)cc2)c(OC)c1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code COc1ccc(\C(=N\O)\c2ccc(N)cc2)c(OC)c1.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6VWW enzyme of corona virus was identified. A pharmacophore equivalent to myricetin obtained from orange plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CCOc1ccc(C(=O)NN)c(O)c1.

Keywords: Corona, Virus, Docking, Pharmacophore

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with myricetin of orange plant. The important enzyme of corona virus chosen was 6VWW.

RESULTS AND DISCUSSION

Table 1 shows that myricetin can block 6VWW enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6VWW. The pharmacophore had SMILES code C[C@H](C[N+](C)(C)C)OC(=O)N. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that myricetin can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6VWW enzyme of corona virus had SMILES code C[C@H](C[N+](C)(C)C)OC(=O)N.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

RESULTS AND DISCUSSION

Table 1 shows that vanillic acid can block 6W4B enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6W4B. The pharmacophore had SMILES code Nc1cc(CCC(=O)O)ccc1O. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code Nc1cc(CCC(=O)O)ccc1O.

The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology : "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

RESULTS AND DISCUSSION

Table 1 shows that vanillic acid can block 6W4B enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6W4B. The pharmacophore had SMILES code C=CCN1CCS(=O)(=O)CC1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code C=CCN1CCS(=O)(=O)CC1.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6W4B enzyme of corona virus was identified. A pharmacophore equivalent to vanillic acid obtained from cocoa plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CCOC(=O)CNC(C)(C)C.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

RESULTS AND DISCUSSION

The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code CNC(=O)Oc1cccc2ccccc12.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6W4B enzyme of corona virus was identified. A pharmacophore equivalent to vanillic acid obtained from cocoa plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CN1C(=O)O[C@H](C1=O)c2ccccc2.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

RESULTS AND DISCUSSION

Table 1 shows that vanillic acid can block 6W4B enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6W4B. The pharmacophore had SMILES code CN1C(=O)O[C@H](C1=O)c2ccccc2. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code CN1C(=O)O[C@H](C1=O)c2ccccc2.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6W4B enzyme of corona virus was identified. A pharmacophore equivalent to vanillic acid obtained from cocoa plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code Oc1cc([O-])nc2ccccc12.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

.RESULTS AND DISCUSSION

Table 1 shows that vanillic acid can block 6W4B enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6W4B. The pharmacophore had SMILES code Oc1cc([O-])nc2ccccc12. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code Oc1cc([O-])nc2ccccc12.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6W4B enzyme of corona virus was identified. A pharmacophore equivalent to vanillic acid obtained from cocoa plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code CC1=NN[C@H](C1)c2ccc(O)cc2.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

RESULTS AND DISCUSSION

Table 1 shows that vanillic acid can block 6W4B enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6W4B. The pharmacophore had SMILES code CC1=NN[C@H](C1)c2ccc(O)cc2. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code CC1=NN[C@H](C1)c2ccc(O)cc2.

The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand. The CDOCK menu

used CHARMm protocol for docking and gave the "-CDOCK Energy and -CDOCK interaction energy". A positive value of both the parameters indicated blocking of active site of viral enzyme [3]. The pharmacophore that was identified had similarity in structure with vanillic acid of cocoa plant. The important enzyme of corona virus chosen was 6W4B.

RESULTS AND DISCUSSION

Table 1 shows that vanillic acid can block 6W4B enzyme of corona virus. A pharmacophore was identified which may cure the disease by blocking the enzyme 6W4B. The pharmacophore had SMILES code CN(C)Cc1oc(CO)cc1. Positive values of "-CDOCK Energy and -CDOCK interaction energy" indicated that the pharmacophore may fight against corona virus. Further wet lab test is required to prove it. However, such analysis may reduce the number of trials. The qualitative and quantitative strengths of interactions between ligands and an enzyme is essential in drug discovery. Reliable estimation of binding interaction may improve the ligand selection. Molecular docking is usually compared to a Lock and Key process. The conformation of the ligand and enzyme does not change during binding. Ligands are often flexible and occupy multiple conformations in solution. CDOCK method considers the multiple conformations and the influence on the interaction. The result shown corresponds to the conformation that resulted in the highest value of - C DOCKER ENERGY.

CONCLUSIONS

The results suggested that vanillic acid can fight against corona virus. "Discovery Studio pharmacophore and Cdock module of Biovia software" suggested that the compound which may deactivate 6W4B enzyme of corona virus had SMILES code CN(C)Cc1oc(CO)cc1.

ABSTRACT

"Corona virus disease 2019 (COVID-19)" causes "severe acute respiratory syndrome" and presently, killed many people worldwide. Researchers are still struggling to find a cure. Pharmacophore analysis followed by molecular docking utilizing "Biovia Discovery studio" were done and the chemical that may deactivate 6W4B enzyme of corona virus was identified. A pharmacophore equivalent to vanillic acid obtained from cocoa plant was identified. Based on positive values of "-CDocker energy as well as -CDocker interaction energy" the drug identified was a compound with SMILES code N[C@H](CO)CC1CCCCC1.

Keywords: Corona, Virus, Docking, Pharmacophore

INTRODUCTION

"Corona virus disease 2019 (COVID-19)" has caused the death of many people all over the world. [1] A new species of corona named as "COVID-19" caused this attack. The issue is that still the researchers are struggling to discover a drug that can prevent corona. [2]. Countries are trying to fight through lockdown. However, that strategy has hit the economy badly. Thus, there is a significant need to develop a treatment for corona. The mankind is doing extensive research to fight back the deadly virus. The goal of the present work is to identify a pharmacophore against corona through *in silico* analysis.

MATERIALS AND METHODS

Methodology: "Biovia Discovery studio CDOCK and Pharmacophore" menu ("Dassault Systemes, France") were utilized. Pharmacophore menu was used to identify a molecule similar to a phytochemical that can deactivate the viral enzyme. Then CDOCK operation was done between an enzyme of the virus and the ligand.
